INDEX TO VOLUME II., 1931.

REFERENCES AND ABBREVIATIONS

Readers in search of a given subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings. Institutions and Corporations with the right to the prefix Royal will be found under that prefix, with the exception of Hospitals, which will be found under that heading; and Medical Societies, which are separately indexed under Societies. All Universities are indexed under the word University. (A.) = Annotation, (C.) = Correspondence, (N.I.) = New Inventions, (L.A.) = Leading Article, (M.L.) = Medico-legal, (M.T.T.) = Modern Technique in Treatment, (O.) = Obituary, (P.I.) = Parliamentary Intelligence, (R.) = Review, (R. and A.) = Reports and Analyses, (N.P.) = New Preparations, and P. and C.P. = Panel and Contract Practice.

Concordance of page numbers and dates of Issue will be found at the end of the Index.

A

bdomen—Management of Abdominal Operations (R. H. Maingot) (R.), 1137
dominal discomfort (A. E. Russell), 1391
bdominal Pain (J. Morley) (R.), 134
bduction treatment in fracture of hip-joint (R. Whitman), 726
bel, A. L., fortnight in North America, 1166
berdeen University Club, London, 1110
borigine, Australian (L.A.), 1416
bortion—and birth-rate, 314; attempted, 1411; criminal, 1134; habitual, treated with wheat-germ oil (P. Vogt-Möller), 182; legalised, in Russia, 1255; Thou Shalt Not Kill (G. Clement) (R.), 1028; *see also* Birth control
brahams, A., headache, 819; and Gordon, I., acute aseptic meningitis, 903
ccidental hæmorrhage, shock following, 742
ccidents—and conveyance to hospital (P.I.), 1328; electrical, in hospitals (A.), 197, 1077
chalasia of cardia, epithelioma of œsophagus in association with (G. Rake, 682
chlorhydric anæmia (D. T. Davies), (L.A.), 409; (H. J. Roper) (C.), 556
dams, E. W. (O.), 825
ddis, T., and Oliver, J., Renal Lesions in Bright's Disease (L.A.), 302
ddison's disease, suprarenal cortex in (A.), 84
Adenoid facies (H. B. Newham) (C.), 825
dmission hospitals, L. G. Brock on (A.), 306
doption of children in Scotland, 1151
drenal glands; *see* Suprarenal
Aeroplanes; *see* Air travel
Æsculapius, the return to, 909
Age, according to birthdays (M.L.), 371
Agramonte, Aristides (A.), 546
Agranulocytosis, 132
Air travel and public health, 591; (A.), 602
Aix-les-Bains, revolving solarium at (H. S. N. Menko) (C.), 554; (L. Wainwright) (C.), 612
Alæ nasi, movement of (A.), 1252
Alajouanine, Th., and Guillain, G., Etudes neurologiques (R.), 966
Albuminuria—in pregnancy (G. F. Gibberd), 520, 576, (C.), 1213, (A. A. Osman) (C.), 714, (G. W. Theobald), 948, (C.), 1156, (L.A.), 969, (A.), 1092; effect of opium on, 605
Alcohol—Alcohol Habit and its Treatment (W. E. Masters) (R.), 915; craving for, 434
Alexander, F. W., reading of Braille by sight (C.), 1104
Alimentary tract, precancerous lesions of (M. J. Stewart), 565, 617, 669, (C.), 1265
Alkalis—treatment of chronic nephritis with (D. M. Lyon, D. M. Dunlop, and C. P. Stewart), 1009
Allen, H. W., excessive spontaneous inflation of lung cavity (C.), 426
Allen, I. M., neurological complications of serum treatment, 1128
Allen's Commercial Organic Analysis (C. A. Mitchell) (R.), 594
Allergy—Recent Advances in Allergy (G. W. Bray) (R.), 1028
Allison, V. D., scarlatinal streptococci without scarlet fever, 844
Alstead, S., and Benn, E. C., diphtheritic hemiplegia, 1131
Aluminium and health (L.A.), 595, (L. Grant) (C.), 662, (A. Francis) (C.), 715
American College of Surgeons, 1037
Amœbiasis in temperate zone (I. Macdonald), 1404; (A.), 1419
Amputating knife, history of (A.), 366
Amytal, properties of, 744
Anæmia—achlorhydric (D. T. Davies), 386, (L.A.), 409, (H. J. Roper) (C.), 556; and polycythæmia, 1357; aplastic (A. G. Gibson), 181; in premature infants, 564; iron in, 133; megaloblastic, in gastro-jejuno-colic fistula (N. H. Fairley and T. P. Kilner), 1335; megaloblastic, non-pernicious, 74; microcytic, 133; nutritional, in infancy (L.A.), 195, (A.), 305; of pregnancy, 1095, in dogs (A.), 1201; secondary, varieties of, and their treatment, 531; vitamin B in (S. Davidson), 1395; *see also* Liver extract
Anæmia, pernicious—brain diet in (C. C. Ungley), 63; cases of, required (L. J. Witts) (C.), 825; injection of highly purified liver preparations in (J. F. Wilkinson), 791, (A.), 807; injection of liver extract in (W. C. Anderson), 1022; reticulocyte crisis in (A.), 1366
Anæsthesia—administration of, 744; apparatus for (I. Lewis) (N.I.), 1304; carbon dioxide after, 742; face-screen for (K. H. Digby), 1294; in second stage of labour (J. King and J. Morgan), 346, (J. Riddell) (C.), 427; premedication for, 742; problem, view of (A.), 1368; progress of, 351; resuscitation during, 795, (A.), 1310; *see also* Amytal, Avertin, Chloroform, Ether, Nitrous oxide, Percaine, Subarachnoid block
Anæsthetics, explosion of (A.), 197, 1077
Anæsthetists to surgical units (A.), 1141; (W. H. Jones) (C.), 1156; (R. H. Mortis) (C.), 1211; (H. N. Webber) (C.), 1211; (R. J. Clausen) (C.), 1268, (C.), 1325
Analyst, public, work of (A.), 696
Anatomist, the (A.), 863
Anatomy—Aids to Surgical Anatomy (R. H. Hunter) (R.), 915; Piersol's Human Anatomy (G. C. Huber) (R.), 538; Short History of Anatomy (R. H. Hunter) (A.), 1418; study of, 869
Anderson, J. R., Detachment of Retina (R.), 800
Anderson, W. C., pernicious anæmia treated by injection of liver extract, 1022
Andrews, C. T., toxic effects of intravenous salyrgan, 131
Angina pectoris, differential diagnosis of (A.), 308
Animals—bequest for sanctuary for (M.L.), 1205; experiment on (P.I.), 46, 436; pedigree, scientific post-mortem examination of (Sir L. Cheatle) (C.), 1323
Ankles, sprained, treatment of (W. E. Tucker), 848
Ankylosis of joints (A.), 644
Ankylostomiasis (A.), 646
Anoxæmia, acute, in acclimatised person (R. Greene), 683
Antenatal—clinics, 185; scheme run by practitioners (A.), 862
Anthelmintic, hexylresorcinol as (A.), 32
Antigen content of serum in disease (A. Q. Wells), 1348
Antiseptics, Sir A. Wright on, 225
Antitoxin—of exceptional potency (A. T. Glenny), 402; in staphylococcal infection (P. N. Panton, F. C. O. Valentine, and V. W. Dix), 1180, (A.), 1198
Ants in hospital, 215
Anuria following pyelography (D. D. Pinnock and I. W. Matheson), 529
Anus—common lesions of (P. L. Daniel), 817; scarification of rugæ of, in Burma, 1377
Aorta, rupture of, 737
Appel, K. E., and Bond, E. D., Treatment of Behaviour Disorders following Encephalitis (R.), 136
Appendicitis—gangrenous (A.), 544; in childhood (D. J. Cannon), 794
Appendix—bacteriology of (Die Bakteriologie der Wurmfortsatzentzündung) (W. Lohr and L. Rassfeld) (R.), 1360; the poisoning (J. McDonnell), 572
Appointments, 54, 105, 170, 220, 276, 331, 380, 432, 511, 667, 722, 777, 832, 882, 942, 998, 1056, 1112, 1164, 1219, 1276, 1334, 1387, 1437
Architects, professional registration of (M.L.), 552

andem, 275
J. A., on transmission of
ease (A.), 974
Armour, D., priority in neurological surgery (C.), 210
Army recruits and physical unfitness (P.I.), 165
Arthritis—Chronic Arthritis and Rheumatoid Affections (B. L. Wyatt) (R.), 76; control and treatment of, 851; osteo-arthritis (P. Figdor), 581, (J. D. Kidd) (C.), 427; rheumatoid, malnutrition factor in (F. D. Howitt and W. F. Christie), 1282, (L. Delicati) (C.), 1434
Artificial respiration, 795; (A.), 1310; (A. Fakhry) (C.), 1325
Asbestos—asbestos-like bodies (F. E. Tylecote and J. S. Dunn), 632; dust, control of, in industry (L.A.), 253
Asbestosis—(P.I.), 1385; complicated by pulmonary tuberculosis (W. B. Wood and S. R. Gloyne), 954; (S. R. Gloyne) (C.), 1193; woman's death from (P.I.), 775
Aschheim-Zondek reaction, 1039, 1152
Asherson, N., iodine powder for chronic otorrhœa, 630
Asphyxia—in nitrous oxide anæsthesia (A. H. Macklin), 897, (C.), 1046, (A.), 921, (D. Belfrage) (C.), 1045; neonatal (A.), 1310; problems of, 795; tartar-emetic and (A. Fakhry) (C.), 1325
Aspiration treatment of laryngeal diphtheria (W. T. Benson), 956
Asthma—bronchial (P. J. Cammidge), 1070, (Sir J. Barr) (C.), 1164; nasal element in, 356; protein in (T. Nelson and A. D. Porter), 1342, (S. Behrman) (C.), 1433; research on (L.A.), 1139, (J. Freeman) (C.), 1212, 1322, (H. W. Barber) (C.), 1266, (G. H. Oriel) (C.), 1267
Atlas, pathological dislocation of, 1298
Atmospheric pollution—Smoke Abatement Handbook, 1111; smokeless coal and (A.), 698

ADDRESSES AND ORIGINAL ARTICLES

TOXIC JAUNDICE.*

BY SIR WILLIAM WILLCOX, K.C.I.E., C.B., C.M.G., M.D., F.R.C.P. LOND.,
PHYSICIAN TO ST. MARY'S HOSPITAL.

(WITH COLOURED PLATE.)

LECTURE I.

DURING the late war the frequent occurrence of toxic jaundice amongst munition workers and those engaged in the manufacture of aeroplanes offered numerous opportunities for close study of the causes and clinical and pathological manifestations of this disease. In the various campaigns all over the world in which our troops played an important part epidemics of toxic jaundice were common. These outbreaks showed that "toxic jaundice" was not limited in its ætiology to chemical poisons, but that toxins of biological origin were even more fertile in its causation.

Since 1919 great advances have been made in our knowledge of the pathology of jaundice, of which perhaps the most important have been the brilliant researches of Hijmans van den Bergh, which have added much to accuracy and precision in diagnosis. The valuable and thoughtful studies of Dr. W. J. McNee have done much to elucidate our knowledge of the causation. The 1929 edition of "Diseases of the Liver and Gall-bladder and Bile-ducts," by Sir Humphry Rolleston and Dr. McNee, has also been of great value in the review and criticism of the recent work on jaundice of toxic origin.

A special reason for my selection of this subject is the frequent occurrence, during the last few years, of delayed, dangerous, and sometimes fatal cases of toxic jaundice due to the administration of recently discovered drugs. One of the most important group of drugs, from this point of view, is the quinophan group, which includes preparations known by the names of Atophan, Cincophen, Phenoquin, Agotan, Atophanyl, and Atoquinol, all of them derivatives of quinoline.

DEFINITION OF JAUNDICE.

Osler gives the following brief but excellent definition in his Text-book of Medicine: "Jaundice or icterus is a condition characterised by coloration of the skin, mucous membrane, and fluids of the body by the bile-pigments." It must be remembered that jaundice is a symptom of some underlying condition which causes an accumulation of bile-pigment (bilirubin) in the blood beyond the normal limits.

This accumulation may be caused, as in "obstructive jaundice," by mechanical obstruction of the common bile-duct or common hepatic duct whereby the bile-pigments are reabsorbed into the blood and lymphatic circulation. In toxic jaundice some toxic factor impairs the excretory power of the liver cells for removing bile from the blood, and often at the same time causes an excessive destruction of red blood corpuscles, with a consequent increased production of bile-pigments. Thus, in attempting to classify the various forms of jaundice, consideration must be given not only to the presence of bile-pigment in the blood in increased amount, but also to the clinical symptoms caused by the underlying condition responsible for the jaundice.

Recent biochemical researches have enabled us to make accurate estimations of the bilirubin in the blood. According to van den Bergh[1,2] normal human serum contains from 1 in 1,000,000 to 1 in 400,000 parts of bilirubin. He gives as 1 unit an amount of 1 in 200,000, so that the normal bilirubin content of the serum would be ½ unit. He showed that there were many conditions in which the bilirubin content might rise to figures from ½ up to 4 or 5 units without clinically definite jaundice of the skin and mucous membranes. This state of the blood has been described as "latent jaundice," and some common examples are pernicious anæmia, chronic hepatic disease such as cirrhosis, and the blood state following the administration of certain drugs, such as arsenobenzol derivatives, which have a known toxic action on the liver and which have not yet produced manifest jaundice.

The bilirubin content of the blood has been also estimated by a method published by Meulengracht in 1921.[3] In this the colour of the serum is matched against a solution of bichromate of potash. A tint corresponding to a solution of 1 in 10,000 is fixed as 1 unit. The colour of the blood-serum is given as so many units according to this scale, and is termed the "icterus index." Normal blood-serum, according to this method, would have a value of 1 to 5 units. In latent jaundice the figure would be from 6 to 15 units. An icterus index of over 15 units would occur when clinically definite jaundice was observable.

False jaundice may occur from the coloration of the skin by dyes of various kinds, such as saffron, turmeric, and trinitrotoluene. It may also occur from taking by the mouth picric acid or other absorbable yellow dyes which stain the tissues. The application of van den Bergh's bilirubin test to the blood-serum would at once differentiate these spurious forms from true jaundice.

CLASSIFICATION OF JAUNDICE.

The simplest and most satisfactory classification is that adopted by Rolleston and McNee—viz.: (1) obstructive hepatic jaundice; (2) toxic and infective hepatic jaundice; (3) hæmolytic jaundice. No classification can be perfect, since the different varieties of jaundice are often combined. Thus in toxic jaundice there is frequently an obstruction to the smaller bile-ducts in the liver as part of the hepatitis set up by the toxic agent. Then, again, hæmolytic jaundice may be combined with toxic jaundice when the toxic agent, such as arseniuretted hydrogen or the toxin of yellow fever, has a destructive action on both the blood and liver cells. It is proposed to include under the term "toxic jaundice" jaundice due to the action of exogenous chemical poisons, or to toxins of extraneous or autogenous biological origin. This will include all of group (2) in the above classification and some types of group (3). It will, of course, include the toxæmias of pregnancy and acidosis, which are associated with jaundice.

In a recent paper Dr. Arnold Rice Rich suggests that the classification of jaundice given above is unsatisfactory, and divides jaundice into two groups:

1. *Retention jaundice*, where an indirect van den Bergh reaction is given. The urine contains no bilirubin or

---

* The Lumleian Lectures delivered before the Royal College of Physicians of London on March 19th, 24th, and 26th, 1931.

bile-salts but increased urobilin, while the stools have increased urobilin. This group includes the various forms of hæmolytic jaundice and jaundice resulting from anoxæmia.

2. *Regurgitation jaundice*, where a positive van den Bergh reaction is given. The urine contains bile-pigment and bile-salts and the stools decreased urobilin. This group includes the various forms of jaundice associated with necrosis of the liver cells—i.e., toxic jaundice of chemical or biological origin as included by me in these lectures, and also the various forms of obstructive jaundice due to mechanical obstruction of the main bile-ducts.

In my opinion the suggested new classification is unsatisfactory because it does not attach sufficient importance to and differentiation of the clinical symptoms of the general underlying cause of the jaundice. Thus the jaundice due to phosphorus poisoning is so essentially different clinically from the jaundice following simple stricture of the common bile-duct that to group these two conditions under the same heading is very undesirable. Then, again, while the jaundice of necrosis of the liver cells may be obstructive in type for a few days and give the laboratory findings of regurgitation jaundice, clinical observation shows that in non-fatal cases these laboratory findings do not persist but quickly change into those partly resembling the so-called retention jaundice.

Another reason which makes this classification unacceptable is that it is based on the variations of the van den Bergh reaction. The present state of our knowledge of this reaction does not admit of a classification of jaundice based on the varieties exhibited by it. Thus, in a discussion on jaundice at the British Medical Association annual meeting in 1924 [6] Dr. van den Bergh was the first to admit that the causation of the variations of his reaction, such as the biphasic and delayed and the indirect type, were not fully understood. Most observers in this country have found that in cases of deep jaundice the van den Bergh reaction is not of much help in the differentiation of the type, since in such cases a marked biphasic reaction is usually given.

Liver Functions in Relation to Toxic Jaundice.

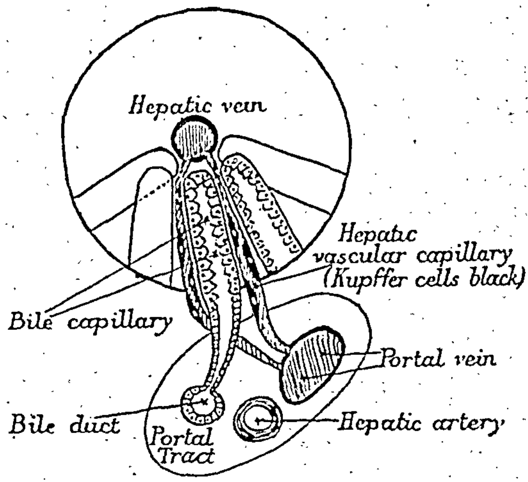
The liver plays a most important part in the body metabolism, and impairment of its metabolic functions quickly leads to toxic symptoms which are commonly accompanied by more or less deep jaundice. The liver cell is the dominant factor in the regulation of the complicated biochemical processes going on in the body. So complex are these processes, and so little understood, that the part played by the liver is probably much more profound than is at present realised. We know that complete suspension of the liver function means speedy dissolution and death in a very few days from auto-intoxication.

BILE.

The theory of bile-pigment production and bile secretion put forward by Dr. McNee in his critical review of jaundice in 1923 is now generally accepted.[7] The diagram from that paper, which is published by his kind permission, illustrates the essential points (Fig. 1). The bile-pigments are produced from hæmoglobin by the destruction of red blood corpuscles in the phagocytic cells of the recticulo-endothelial system, these cells being known as Kupffer cells. It is known that this destruction of red blood corpuscles takes place in the Kupffer cells in the liver, spleen, and bone-marrow. It is in these cells that bilirubin is produced. The bilirubin circulates in the hepatic capillaries, and passes from them into the bile capillaries lying in the centre of the liver tubules. If the liver cells are healthy the bilirubin passes through them and becomes combined in some loose way with bile-salts and cholestrin. This association of the bilirubin prevents its adsorption by the proteins of the plasma, and bilirubin in this state will give a direct van den Bergh reaction.

In some conditions—for example, in anoxæmia of the liver cells whereby their function is seriously impaired—the bilirubin from the hepatic capillaries cannot be fully absorbed by the damaged liver cells, and as a consequence it remains in the blood stream, entering into physical combination with the proteins of the plasma. In this condition the blood-serum only gives a van den Bergh reaction after treatment with alcohol, whereby the bilirubin is separated from the plasma proteins. In other words, an "indirect ven den Bergh" reaction occurs. This condition of things happens in acholuric jaundice and in various forms of hæmolytic jaundice, especially when associated with anæmia which causes anoxæmia of the liver cells.

FIG. 1.



A liver lobule (diagrammatic).

"FAT METABOLISM."

Normally a certain amount of fat is stored up in the liver cells, and this consists mainly of unsaturated fatty acids in organic combination. In conditions of toxic jaundice fatty degeneration is often a marked feature, and the liver cells become engorged with fat. This fat differs chemically from the fat deposited in the liver cells under normal physiological conditions. It is composed of saturated fatty acids in organic combination.

Very marked fatty degeneration and distension of the liver cells with fat is met with in toxic jaundice from such chemical poisons as chloroform, phosphorus, alcohol, trinitrotoluene, and tetrachlorethane; it is also seen in the toxic jaundice associated with acute or subacute hepatic necrosis or with conditions of auto-intoxication such as acidosis or the toxæmias of pregnancy. A. G. R. Foulerton published an interesting paper on this subject in 1918.[8]

"GLYCOGEN FUNCTION."

The presence of glycogen in the liver cells seems to increase their power of resistance to toxic agents. Glycosuria has sometimes been observed in toxic jaundice. Garrod [13] has recorded a case of glycosuria in catarrhal jaundice, and glycosuria has been observed in the toxic jaundice of phosphorus, chloroform, and other poisons.

As a converse to this, an interesting case was reported by J. Bordley.[9] A patient, aged 47, who had suffered for eight years from severe diabetes mellitus, at the end of this period developed hepatic cirrhosis with ascites. At this stage the blood-sugar became normal and the diabetes disappeared. Claude Bernard recorded a similar case in 1877, where a man, aged 55, lost the symptoms of diabetes mellitus at the onset of portal cirrhosis and ascites.

PROTEIN METABOLISM.

The most important function of the liver is the part its cells play in breaking down the complex products of protein metabolism, many of which have powerful toxic properties, into simple nitrogenous compounds such as urea, uric acid, creatinine, and hippuric acid, which are eliminated by the kidney. When the liver cells are so damaged by the action of chemical or biological poisons that this function is impaired, symptoms of the gravest kind may set in and death result from the rapidly developing auto-intoxication caused by the toxic effects of the complex intermediate products of protein metabolism.

TOXIPHYLACTIC FUNCTION.

A most important function of the liver is its protective function, whereby the body is protected against exogenous poisons. The term "toxiphylactic function" was suggested by me in 1922.[10]

If the poison is absorbed by the alimentary tract it is conveyed by the portal vein to the liver, which absorbs much of the poison and acts as the first line of defence. When the poisons are introduced into the general circulation as, for example, the intravenous injection of arsenobenzol derivatives, the liver absorbs much of the poison from the blood stream and so protects the other tissues of the body. In exerting its prophylactic function the liver itself often suffers severely, and its cells may undergo fatty degeneration, cloudy swelling, or even extensive necrosis. In addition, an inflammation of the interstitial tissues may be set up and a progressive hepatitis with fibrosis result. In cases of fatal poisoning, whether from mineral poisons such as arsenic and lead, or from organic poisons such as morphine and strychnine, the greater part of the poison is found in the liver and this organ is the most important for reservation for analysis. The poison found in the liver is poison which has already exerted its toxic effect on the body, whereas that found in the alimentary tract is unabsorbed and has not exerted its toxic effects on the tissues of the various body organs.

A striking example was the Maybrick case, where the deceased had lived for several days after the administration of arsenic. In this case no arsenic was found in the stomach, and a trace only in the kidneys, *while the liver contained about gr. ½.*

It is important to remember that some poisons, which are rapidly eliminated or which may undergo oxidation in the body, may irreparably damage the liver, so that it undergoes extensive necrosis and death results several days after the taking of the poison. The terminal symptoms are due to the endogenous poisons consequent on cessation of liver function, not to the continued action of the exogenous poisons originally taken. Examples of this are phosphorus, delayed chloroform poisoning, and tetra-chlorethane poisoning. In such cases no trace of the original chemical poison may be expected to be present in the body at the time of death.

Liver Function Tests.

Much work has been done in attempting to discover a satisfactory test for liver function analogous, for example, to the blood-urea test for renal function. At the present time, it must be admitted, most of the tests for hepatic function are unsatisfactory in that they fail to indicate the impending danger of that complete breakdown of hepatic function which usually *terminates fatally in a very few days.*

The *van den Bergh test* and the *icterus index* are of value in indicating the bile-regulating mechanism of the liver, but this is not the function of vital importance. High values of these tests are not necessarily indicative of complete breakdown of hepatic function. It is the function of the hepatic cells which it is so necessary to determine. The liver is very uniformly supplied with blood and the loss of function of the hepatic cells is nearly always due to the flood of toxins carried to them by the blood stream. The individual liver cells are therefore submitted to the same toxic influences; in other words, they stand or fall all together. This explains the fact that many of the tests do not show a positive indication of loss of hepatic function until too late —i.e., until a condition of acute and fatal necrosis has set in.

The *lævulose test* is, in my experience, the most valuable and sensitive test, and that which best shows early impairment of function. The healthy liver can dispose of 50 g. of lævulose taken by the mouth so that there is no rise of blood-sugar. If the cells are impaired in function a definite rise occurs.

The *phenoltetrachlorphthalein* and *bromsulphalein tests.*—One of these substances is injected intravenously in calculated amount. If hepatic function is normal practically no dye will be left in circulation after half an hour. Where the liver function is impaired, appreciable quantities of the dye remain in circulation. These tests have found much favour in America. They are well described by Dr. G. A. Harrison.[11]

The lipase test, the fibrinogen test, the nitrogen partition test, and other tests have been found to be of little or no clinical value. They are subject to other influences than variation in hepatic function, and marked results are only given when it is too late—i.e., when an extreme degree of hepatic necrosis has developed.

Morbid Anatomy and Histology.

In toxic jaundice the liver may be greatly enlarged and on section show a striking yellow appearance, due to the excessive deposition of fat in the liver cells, and pieces of such livers may float in water. This type of liver is seen in delayed chloroform poisoning, in the fatal acidosis of children, in phosphorus poisoning where death occurs early, and in some cases of alcoholism.

I was informed by the late Sir Norman Moore, who was an acknowledged authority on both medicine and literature, that the term "cirrhosis" was originally applied to livers showing a marked yellow appearance, and that etymologically this is the correct application of the term, for it is derived from the Greek word "kirros," meaning reddish yellow or tawny. Of late years the term "cirrhosis" has become restricted to livers showing fibrotic changes such as occur in the portal cirrhosis of alcoholism.

Acute and subacute necrosis of the liver is the most common condition found in fatal toxic jaundice. It is described below under "necrosis of the liver."

The following microscopical changes are seen:—

(1) *Cell degeneration.*—The liver cells commonly show extensive fatty degeneration and are distended with fat. In some cases marked cloudy swelling is observed.

(2) *Necrosis of liver cells.*—The cells may be necrosed and granular, their nuclei having disappeared, or the cells may have entirely disintegrated and disappeared.

(3) Fibrous tissue may have developed in areas formerly occupied by liver cells (replacement fibrosis).

(4) Active progressive fibrosis with round-cell infiltration may be present.

(5) Regeneration of liver cells may occur in the less severe cases. The regenerated cells do not form themselves into the architectural structure of physiological lobules but are isolated masses of liver cells.

(6) Proliferation of the cells of the bile canaliculi may occur in the less acute cases.

Illustrations and Cases.

The accompanying coloured plate reproduces drawings of microscopical sections from six recent fatal cases of toxic jaundice, and these illustrate all the important points. The cases may be briefly summarised as follows:—

CASE 1.—*Phosphorus poisoning.* (P.M. 141/29.) Male, aged 22. Admitted to St. Mary's Hospital two hours after taking rat poison (phosphorus). Continued vomiting occurred. After three days jaundice developed and deepened, the liver became enlarged, the stools were clay-coloured. Death followed six days after taking the poison. The liver was found to weigh 1850 g. The cut surface was bright yellow with several subcapsular hæmorrhages. Microscopically there were extreme fatty changes more marked at periphery of lobules where cells have lost their nuclei and are represented by large fatty globules. (See Plate, Fig. I.) Stained with hæmatoxylin and Sudan III. (× 60.)

CASE 2.—*Cirrhosis of liver following novarsenobillon injections.* (P.M. 4/29.) Male, aged 63. Ten injections of 0·6 g. novarsenobillon given in February and March, 1928, the last on March 25th. On August 1st, 1928, jaundice developed; this was followed by ascites, paracentesis abdominalis being performed nine times. Wassermann reaction negative; van den Bergh reactions biphasic. Death on Jan. 3rd, 1929. At autopsy the liver was small (900 g.) with a thickened capsule. On section it had a finely granular surface with yellow areas of regeneration nodules and intervening greyish fibrous tissue.

Microscopical examination showed a thickened capsule; large numbers of proliferating bile-ducts; round-celled infiltration and young fibrous tissue; and liver cells, some regenerating and some dying—many containing bile. (Fig. II.) Stained with hæmatoxylin and eosin. (× 60.)

CASE 3.—*Subacute necrosis, toxic jaundice.* (P.M. 228/26.) Male, aged 58. Malaise from Nov. 15th, 1926. On Nov. 22nd, 1926, nausea and vomiting, hepatic discomfort. On the 25th, jaundice set in, which rapidly deepened. On the 27th, the patient was delirious, the stools were pale, and van den Bergh's reaction was biphasic. The Wassermann reaction was negative. The urine contained albumin, granular and hyaline casts. On Dec. 2nd coma developed and death occurred on the 5th. The liver was small (950 g.), soft, and flabby with a mottled yellow and grey surface. On section it was yellow with a few red areas. The microscopical section shows dilatation of sinusoids in areas where liver cells have died and been autolysed. The remaining liver cells have undergone fatty changes and many contain bile. (Fig. III.) Stained with hæmatoxylin and eosin. (× 95.)

CASE 4.—*Alcoholic cirrhosis.* (P.M. 101/26.) Female, aged 54. History of chronic alcoholism for over ten years. Ascites. Paracentesis abdominalis twice in 1926. On June 15th, 1926, hæmatemesis; death on June 18th. The liver was small (1325 g.) and pale, with a coarsely granular hobnailed surface. Section showed coarse strands of pale fibrous tissue uniformly distributed throughout the organ. The spleen was enlarged. Microscopical examination showed regeneration nodules surrounded by fibrous and elastic tissue. Also much fat in the liver cells. (Fig. IV.) Stained with hæmatoxylin, Weigert's elastic stain, and Sudan III. (× 60.)

CASE 5.—*Eclampsia. Toxic jaundice.* (P.M. 66/28). Female, aged 41. Admitted in coma following a fit in the first stage of labour, slightly jaundiced. Died 29 hours after delivery. Post-mortem: the liver was large (1600 g.) and swollen, with several subcapsular hæmorrhages. On section the cut surface swelled over the capsule and had numerous irregular greyish-yellow necrotic areas surrounded by hæmorrhage. The microscopical section includes a focus (near a portal system not shown in drawing) of necrotic liver cells surrounded by a zone of fatty cells and hæmorrhage. The liver cells show cloudy swelling. (Fig. V.) Stained with hæmatoxylin and Sudan III. (× 90.)

CASE 6.—*Delayed chloroform poisoning.* Girl, aged 17. Admitted to hospital for difficult labour April 21st, 1928. On April 22nd, anæsthetic (chloroform), forceps delivery. On April 23rd, patient drowsy, general condition good. Next day slight jaundice, very drowsy, restless, noisy, knee-jerks exaggerated. Plantar reflex showed extensor responses, some rigidity and spasm of muscles. In evening coma, eyes moving laterally, twitchings of muscles. Jaundice increased. Urine had trace of albumin and some diacetic acid. Death on April 25th. At autopsy the liver was found to be enlarged, soft, and flabby (weight 1800 g.). The colour was yellow with a lobular pattern and subcapsular reddish spots. On section cut surface swelled over capsule. There were yellow areas round central veins of lobules surrounded by red areas, and the periphery of the lobules was grey. Near the hilum there were large areas of yellow necrotic tissue where whole lobules are necrotic. Microscopically central necrosis is seen; the periphery of lobules shows fatty degeneration. (Fig. VI.) Hæmatoxylin and Sudan III. (× 75.)

Pathology of Toxic Jaundice.

From the morbid conditions resulting from the pathological changes caused by the toxic agents which cause toxic jaundice it is clear that the dominant factor in the causation of clinical effects is the damage to the liver cell.

The intensity of the jaundice in any given case is no criterion of the clinical symptoms or of the prognosis as regards life in any given case. Jaundice may be very deep and yet recovery may be complete, without dangerous symptoms supervening, as is seen in epidemic catarrhal jaundice; on the other hand, jaundice may be slight, and dangerous symptoms followed by death may rapidly develop, as in delayed chloroform poisoning and the toxæmias of pregnancy.

Many factors have to be considered, and it must be borne in mind that the same poison may produce any of the morbid histological changes in the liver already described. In one patient this poison may exert its toxic influence *directly on the liver cells*, causing fatal loss of function, while the same poison in another case may exert a less severe action on the liver cells but produce changes in the bile-ducts and intrahepatic fibrous tissue. In the former case jaundice may be slight and death rapid, while in the latter jaundice may be marked and death delayed or averted. This condition of things is well illustrated in poisoning from arsenobenzol derivatives.

The factors to be considered are the poison, idiosyncrasy, and the time factor.

THE POISON.

Some poisons exert a profound and rapid action on the liver, for example, phosphorus, and death rapidly supervenes, with jaundice of varying degree. Arsenobenzol derivatives, such as salvarsan, may occasionally display this intensive action on the liver cells, causing death in a very few days with symptoms of profound auto-intoxication and only slight jaundice. On the other hand, the symptoms from this group of poisons may be delayed, and deep jaundice may result without dangerous clinical symptoms. The explanation of the variation in action must be the histological damage caused in the liver, and it is clear that this damage is not constant in type for the same poison.

While poisons vary much in their intensity of toxic action on the liver—for example, chloroform is much more toxic than alcohol in its hepatic effects—yet the intensity of action is so variable in different individual cases that the prognosis must always be very guarded when symptoms of toxic jaundice develop, whatever the poison may be. *Epidemic*

SIR WILLIAM WILLCOX: TOXIC JAUNDICE.

The following microscopical changes are seen :—

(1) *Cell degeneration.*—The liver cells commonly show extensive fatty degeneration and are distended with fat. In some cases marked cloudy swelling is observed.

(2) *Necrosis of liver cells.*—The cells may be necrosed and granular, their nuclei having disappeared, or the cells may have entirely disintegrated and disappeared.

(3) Fibrous tissue may have developed in areas formerly occupied by liver cells (replacement fibrosis).

(4) Active progressive fibrosis with round-cell infiltration may be present.

(5) Regeneration of liver cells may occur in the less severe cases. The regenerated cells do not form themselves into the architectural structure of physiological lobules but are isolated masses of liver cells.

(6) Proliferation of the cells of the bile canaliculi may occur in the less acute cases.

Illustrations and Cases.

The accompanying coloured plate reproduces drawings of microscopical sections from six recent fatal cases of toxic jaundice, and these illustrate all the important points. The cases may be briefly summarised as follows :—

CASE 1.—*Phosphorus poisoning.* (P.M. 141/29.) Male, aged 22. Admitted to St. Mary's Hospital two hours after taking rat poison (phosphorus). Continued vomiting occurred. After three days jaundice developed and deepened, the liver became enlarged, the stools were clay-coloured. Death followed six days after taking the poison. The liver was found to weigh 1850 g. The cut surface was bright yellow with several subcapsular hæmorrhages. Microscopically there were extreme fatty changes more marked at periphery of lobules where cells have lost their nuclei and are represented by large fatty globules. (See Plate, Fig. I.) Stained with hæmatoxylin and Sudan III. (× 60.)

CASE 2.—*Cirrhosis of liver following novarsenobillon injections.* (P.M. 4/29.) Male, aged 63. Ten injections of 0·6 g. novarsenobillon given in February and March, 1928, the last on March 25th. On August 1st, 1928, jaundice developed; this was followed by ascites, paracentesis abdominalis being performed nine times. Wassermann reaction negative; van den Bergh reactions biphasic. Death on Jan. 3rd, 1929. At autopsy the liver was small (900 g.) with a thickened capsule. On section it had a finely granular surface with yellow areas of regeneration nodules and intervening greyish fibrous tissue.

Microscopical examination showed a thickened capsule; large numbers of proliferating bile-ducts; round-celled infiltration and young fibrous tissue; and liver cells, some regenerating and some dying—many containing bile. (Fig. II.) Stained with hæmatoxylin and eosin. (× 60.)

CASE 3.—*Subacute necrosis, toxic jaundice.* (P.M. 228/26.) Male, aged 58. Malaise from Nov. 15th, 1926. On Nov. 22nd, 1926, nausea and vomiting, hepatic discomfort. On the 25th, jaundice set in, which rapidly deepened. On the 27th, the patient was delirious, the stools were pale, and van den Bergh's reaction was biphasic. The Wassermann reaction was negative. The urine contained albumin, granular and hyaline casts. On Dec. 2nd coma developed and death occurred on the 5th. The liver was small (950 g.), soft, and flabby with a mottled yellow and grey surface. On section it was yellow with a few red areas. The microscopical section shows dilatation of sinusoids in areas where liver cells have died and been autolysed. The remaining liver cells have undergone fatty changes and many contain bile. (Fig. III.) Stained with hæmatoxylin and eosin. (× 95.)

CASE 4.—*Alcoholic cirrhosis.* (P.M. 101/26.) Female, aged 54. History of chronic alcoholism for over ten years. Ascites. Paracentesis abdominalis twice in 1926. On June 15th, 1926, hæmatemesis; death on June 18th. The liver was small (1325 g.) and pale, with a coarsely granular hobnailed surface. Section showed coarse strands of pale fibrous tissue uniformly distributed throughout the organ. The spleen was enlarged. Microscopical examination showed regeneration nodules surrounded by fibrous and elastic tissue. Also much fat in the liver cells. (Fig. IV.) Stained with hæmatoxylin, Weigert's elastic stain, and Sudan III. (× 60.)

CASE 5.—*Eclampsia. Toxic jaundice.* (P.M. 66/28). Female, aged 41. Admitted in coma following a fit in the first stage of labour, slightly jaundiced. Died 29 hours after delivery. Post-mortem: the liver was large (1600 g.) and swollen, with several subcapsular hæmorrhages. On section the cut surface swelled over the capsule and had numerous irregular greyish-yellow necrotic areas surrounded by hæmorrhage. The microscopical section includes a focus (near a portal system not shown in drawing) of necrotic liver cells surrounded by a zone of fatty cells and hæmorrhage. The liver cells show cloudy swelling. (Fig. V.) Stained with hæmatoxylin and Sudan III. (× 90.)

CASE 6.—*Delayed chloroform poisoning.* Girl, aged 17. Admitted to hospital for difficult labour April 21st, 1928. On April 22nd, anæsthetic (chloroform), forceps delivery. On April 23rd, patient drowsy, general condition good. Next day slight jaundice, very drowsy, restless, noisy, knee-jerks exaggerated. Plantar reflex showed extensor responses, some rigidity and spasm of muscles. In evening coma, eyes moving laterally, twitchings of muscles. Jaundice increased. Urine had trace of albumin and some diacetic acid. Death on April 25th. At autopsy the liver was found to be enlarged, soft, and flabby (weight 1800 g.). The colour was yellow with a lobular pattern and subcapsular reddish spots. On section cut surface swelled over capsule. There were yellow areas round central veins of lobules surrounded by red areas, and the periphery of the lobules was grey. Near the hilum there were large areas of yellow necrotic tissue where whole lobules are necrotic. Microscopically central necrosis is seen; the periphery of lobules shows fatty degeneration. (Fig. VI.) Hæmatoxylin and Sudan III. (× 75.)

Pathology of Toxic Jaundice.

From the morbid conditions resulting from the pathological changes caused by the toxic agents which cause toxic jaundice it is clear that the dominant factor in the causation of clinical effects is the damage to the liver cell.

The intensity of the jaundice in any given case is no criterion of the clinical symptoms or of the prognosis as regards life in any given case. Jaundice may be very deep and yet recovery may be complete, without dangerous symptoms supervening, as is seen in epidemic catarrhal jaundice; on the other hand, jaundice may be slight, and dangerous symptoms followed by death may rapidly develop, as in delayed chloroform poisoning and the toxæmias of pregnancy.

Many factors have to be considered, and it must be borne in mind that the same poison may produce any of the morbid histological changes in the liver already described. In one patient this poison may exert its toxic influence directly on the liver cells, causing fatal loss of function, while the same poison in another case may exert a less severe action on the liver cells but produce changes in the bile-ducts and intrahepatic fibrous tissue. In the former case jaundice may be slight and death rapid, while in the latter jaundice may be marked and death delayed or averted. This condition of things is well illustrated in poisoning from arsenobenzol derivatives.

The factors to be considered are the poison, idiosyncrasy, and the time factor.

THE POISON.

Some poisons exert a profound and rapid action on the liver, for example, phosphorus, and death rapidly supervenes, with jaundice of varying degree. Arsenobenzol derivatives, such as salvarsan, may occasionally display this intensive action on the liver cells, causing death in a very few days with symptoms of profound auto-intoxication and only slight jaundice. On the other hand, the symptoms from this group of poisons may be delayed, and deep jaundice may result without dangerous clinical symptoms. The explanation of the variation in action must be the histological damage caused in the liver, and it is clear that this damage is not constant in type for the same poison.

While poisons vary much in their intensity of toxic action on the liver—for example, chloroform is much more toxic than alcohol in its hepatic effects —yet the intensity of action is so variable in different individual cases that the prognosis must always be very guarded when symptoms of toxic jaundice develop, whatever the poison may be. *Epidemic* examination on June 24th showed no more change, the condition in the lungs being practically the same as that on the first examination in April. Dr. Stanley Melville, however, made the suggestion that the appearances were similar to those seen in cases of blastomycosis. A later skiagram showed that there was no anterolateral compression of the trachea.

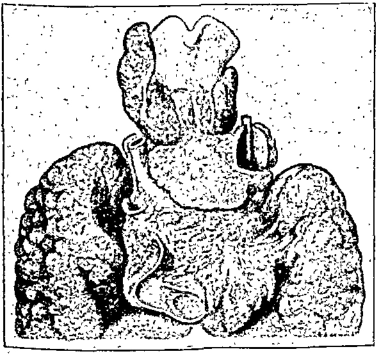
In view of the radiological appearances and the suggestion that enlargement of the thyroid might be the cause of the tracheal stenosis, an attempt was made under a local anæsthetic to investigate the condition of the gland, with a view to removing, if possible, some portion of it or at least dividing the isthmus in order to relieve pressure. Unfortunately the patient's mental and physical condition rendered the undertaking impossible, and the operation had to be abandoned. A small portion of tissue removed showed only fibrous and muscular structure, with no glandular elements.

The girl's condition gradually deteriorated. Her weight decreased, the dyspnœa became more severe, and she was quite unable to stand or even to sit up in bed without grave distress. She went home on Jan. 23rd, 1930, at her mother's desire. She was readmitted for the last time on August 18th, on account of urgent suffocative attacks. She was now extremely emaciated and definitely cyanotic, having to lie propped up in bed and unable to make the least movement. There was some clubbing of the fingers. The chest was extraordinarily flattened from before backwards, and the whole front of the thorax receded with every inspiration, the lower ribs expanding a little in a lateral direction at the same time. There was no enlargement of the liver and no œdema of the legs or albuminuria. The pulse-rate was 112–124, and the respiration-rate 28–34. She died suddenly in an attack of dyspnœa on August 27th, 1930.

POST-MORTEM FINDINGS.

The body was extremely emaciated. There was no œdema of the legs. No enlarged glands were present in the neck. The right lobe of the thyroid gland was much larger than the left. Immediately below the thyroid, but not continuous with it, a firm mass was found which, as will be seen in Fig. 2, was in close relation to the right carotid sheath, and completely surrounded the left carotid sheath. The main bulk of the growth was to the left of the midline, and this portion pressed inwards on the left side of the trachea. On opening the trachea the lumen was found to be markedly stenosed about 1½ inches above its bifurcation. The growth had not, however, infiltrated the tracheal wall.

FIG. 2.



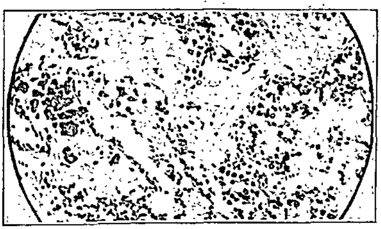
Drawing showing relative size and position of tumour.

There were many fine adhesions between the pericardium and the pleura over the apex of the left lung. The right auricle and ventricle were very dilated. There was no valvular disease. The lungs were small and their surface irregularly puckered. They felt indurated, but some portions, especially in the upper lobes, contained air. On section they presented a congested appearance and oozed blood freely, but throughout the lung substance were seen denser areas of varying size, the average being less than half an inch in diameter. These areas felt indurated and airless, and sank in water. This condition was most marked around the hilum and in the lower lobes, where there appeared to be no normal lung tissue present.

The mediastinal glands were not enlarged. The liver was soft, but there was no nutmeg congestion. No secondary deposits were present. The spleen and kidneys appeared normal.

Sections were made from (*a*) the growth, (*b*) from both lungs, (*c*) from a mediastinal gland. We are indebted to Prof. E. H. Kettle for the following report on the sections :—

FIG. 3.



Section of the tumour. (× 100.)

"The condition is a neoplasm and not an inflammatory or hyperplastic process. I do not think there is evidence that it started in the thymus in the sense that it is composed of specific thymus tissue. The growth contains small calcareous foci (see Fig. 3), but I do not think these represent degenerated thymus corpuscles, but are possibly due to the degeneration of small groups of tumour cells. The dense hyaline stroma suggests a chronic process. As to the actual nature of the growth, I would suggest an endothelioma—derived from vascular endothelium—a hæmangio-endothelioma. Most of the tumour cells consist of little else than small nuclei, but here and there one sees groups of cells which have a definite amount of cytoplasm, and these cells are closely applied to each other. The cells lie in spaces in the stroma in which they are very loosely packed, an arrangement due, I believe, to a primary cell degeneration. I suggest that these cells represent primitive angioblasts which, by a physiological degeneration, tend to produce vascular spaces within their own groups. And I think I can trace this development throughout all its stages in the section."

Pathology of the Tumour.

That the tumour was situated in the thymus is sufficiently proved by its anatomical position and by the presence of normal thymic tissue attached to its lower pole. Probably more of this might have been found elsewhere if the growth had been thoroughly examined and not preserved practically entire, as it was, for the hospital museum. Its malignancy was indicated by the secondary deposits in the neighbouring glands and in the lungs. As it was not apparently composed of thymic elements, it should perhaps be described as *in* the thymus rather than *of* it.

Tumours of the thymus seem to have been first described by Friedleben in 1858, and were well known to Virchow, who noted that the gland was often the starting-point of lymphosarcoma (Voges [1]). Simple tumours, such as fibroma and myxoma, are said to occur in it, and also cysts of various kinds, both developmental and dermoid (Ewing [2]). Lipoma of the thymus is a pathological curiosity; two cases are noted by Yamanoi,[3] and a unique case of mixed tumour (cystadeno-chondrosarcoma), analogous to those met with in the parotid and testicle, was described by Rolleston.[4] Mandelbaum and Celler described a case of tumour which they regarded as a "perilymphatic lymphangio-endothelioma" (Bell [5]). Statistical knowledge of tumours of the thymus practically dates from a paper by Rubaschow (1911), who collected 69 cases. Of these 52 were classed as sarcoma and 12 as carcinoma, with 5 doubtful. Among the sarcomata, lymphosarcoma largely predominated (26 cases being called lymphosarcoma or lymphoma), the remainder including round-celled, spindle-celled, and mixed-celled growths, and one specimen described as sarcoma cavernosum. Two of the sarcomata (recorded by Letulle) were called lymphadenoma, a matter of interest in view of the division of lymphosarcomata by Symmers and Vance [6] into (1) a variety consisting of masses of lymphoid cells, separated by strands of connective tissue (apparently the kind of growth usually described as lymphosarcoma); and (2) tumours histologically resembling Hodgkin's disease, containing giant-cells and eosinophil elements. Gandy and Piédelièvre [7] describe as lymphadenoma a growth which actually infiltrated neighbouring parts, including the heart and the superior vena cava.

The carcinomata of the thymus have been the subject of considerable discussion, as they present peculiar characteristics. Rubaschow noted that one form of cancer may be ill-defined and closely resemble sarcoma, while a second variety takes the form of ordinary "medullary" carcinoma. Other writers speak of small-celled and large-celled varieties of carcinoma of the thymus, and a form of tumour special to this gland (also found in the tonsil) is the so-called lympho-epithelioma, which exhibits a reticulum of epithelial cells containing within its alveoli masses of lymphoid elements. As consisting of the two forms of cells met with in the normal thymus, epithelial and lymphoid, this form of growth may merit the name "thymoma," which has been loosely applied to different forms of growth originating in the gland, including the lymphosarcomata. Pure epithelial tumours or epitheliomata are said to be the rarest form of thymic growth. Symmers and Vance [6] state that only four cases are on record, including one of their own. A case reported by Strauss,[8] not included in their list, is called "squamous carcinoma." Foot and Harrington [9] add a further case which they prefer to term "thymic epiblastoma." Zajewloschin,[10] who attributes the division of carcinomata into small-celled and large-celled varieties to Schmincke, notes that the former were called sarcomata by Letulle; on the other hand, Davidson quotes the recent view of Barnard that many of the tumours in the mediastinum called lymphosarcomata are in reality a form of carcinoma. The only conclusion possible appears to be that the classification of tumours according to their histological appearances is at present unsatisfactory, and that those arising in the thymus, owing to its peculiar histological structure, present peculiar difficulties.

A search, throughout such medical periodicals as were available to us, for cases of tumour of the thymus recorded in the last 12 years (1919–30) does not bear out the relative proportions of the different growths met with by Rubaschow. Possibly more attention has been devoted recently to the carcinomata, as being rarer and so of greater interest; or perhaps, more probably, the basis of classification has changed, many growths previously regarded as lymphosarcomata being now called lympho-epitheliomata. Be that as it may, of 43 instances of which we find adequate records 29 were (so far as we can judge) carcinomata and 14 sarcomata, 10 of the latter being lymphosarcomata. Of the carcinomatous tumours 12 were apparently lympho-epitheliomata, 13 were described simply as carcinomata, and 4 as epitheliomata. The various authors themselves seem to find the differentiation difficult, and the descriptions given are not always easy to follow. The numbers must therefore be regarded as only approximate. Further, we cannot regard the classification itself as free from doubt, in view of the nature of our own specimen, which at first sight definitely suggested a carcinoma and which was so regarded by several pathologists who kindly looked at our sections. The true nature of this tumour was only determined after careful study by Prof. E. H. Kettle, who has devoted much attention to growths derived from the vascular endothelium. It seems not impossible that some of the tumours previously called carcinomata were in reality of the same nature.

Large multinucleate cells resembling giant-cells, and masses like syncytia, have been found in epithelial as well as in sarcomatous tumours of the thymus. Calcification is also commonly found, as in our own specimen. Hassall's corpuscles may or may not be present; their absence does not negative an origin in the thymus gland.

Metastases occur most frequently in the neighbouring lymphatic glands, in the pleuræ, and in the lungs. They may, however, occur at a distance, and have been found in the abdominal glands, the liver, the kidneys, the suprarenal bodies, the stomach, the ovary, and rarely in the bones. They may resemble the parent tumour in containing Hassall's corpuscles and areas of calcification. In one instance the thyroid gland was the seat of a secondary deposit (S. E. Brown [11]).

Symptomatology.

It is not very rare for a tumour of the thymus to be found unexpectedly at necropsy, having given rise to no symptoms during the patient's life. In most cases, however, there is dyspnœa of increasing intensity, often paroxysmal in character, along with cyanosis and œdema of the neck and face, due to pressure on venous trunks. The vena cava superior may be compressed or even penetrated by the growth; the bronchial vessels may also be involved, with resulting hæmoptysis, and in one case a bronchus itself was obstructed by growth. Pleurisy with effusion is not uncommon, and the fluid may be hæmorrhagic; pneumothorax has also been encountered. The pericardium may be involved in the tumour, and even the muscle of the heart may be invaded.

Radiographic examination generally shows a dense shadow extending outwards on either side of the manubrium sterni and downwards into the thorax. In rare instances metastases have given rise to the most prominent symptoms. Thus in one instance enlarged abdominal glands gave rise to a diagnosis of abdominal tumour, and in another, in which the spine was the seat of secondary growth, a paraplegic condition occurred before the primary disease was recognised. A remarkable instance of thymic lympho-epithelioma in which there were metastases in the brain and choroid plexus was recorded by Danisch and Nedelmann,[12] the patient being a child aged 3½ years. A still earlier case is described by Bedford [13] in a new-born baby, the carcinomatous growth causing death by asphyxia, with metastases in the lungs, liver, bones, and skin, these last being indicated by a cutaneous eruption during life.

It is usually stated that sarcomata occur in young patients and carcinomata in older subjects, but the above instances show that the rule is far from absolute. Foot and Harrington [9] also met with an epithelial tumour in a female child aged 2 years. Among the cases which we have collected there were 18 instances of carcinoma in persons over the age of 40, and ten below that age. The sarcomata were more evenly distributed, there being three in the first decade of life, two in the second, three between 21 and 30 years of age, and three between 31 and 40, the remaining two being in persons aged 60. The association of thymic tumours with other diseases is of interest. Friedlander and Foot [14] recorded a case of small round-celled sarcoma in a woman of 38, accompanied by lymphatic leukæmia; they infer that the growth must have been a lymphosarcoma owing to this association—possibly a doubtful argument. The question of the relationship between enlargement of the thymus and this form of leukæmia is discussed by Major,[15] who mentions that Lochte described an "epithelioid transformation" of the gland in acute cases. Bell [5] collected a series of cases of thymic tumours occurring in patients suffering from myasthenia gravis, most of which he regards as having been benign in character, though they were not always so described by the original authors, the lymphorrhages characteristic of myasthenia having been sometimes mistaken for secondary deposits of sarcoma. One case, however, in his series was a genuine round-celled sarcoma with secondary growths in the pleura and diaphragm. An association of thymic tumour with tuberculosis was noted in two instances, but must probably be regarded as accidental. A previous history of attacks of tonsillitis, such as occurred in our own case, is given in the case described by Friedlander and Foot,[14] and Foot and Harrington [9] in another case found the tonsils hypertrophic. In a case reported by Ewing, repeated attacks of tonsillitis had occurred. In view of the frequency of tonsillar inflammation the association in these patients was probably accidental, but the close resemblance in histological structure between the tonsil and the thymus, and the occurrence of lympho-epitheliomata in both these organs, render the association worthy of note.

Diagnosis.

In most cases of thymic tumour the radiographic appearances, along with dullness on percussion over the upper part of the sternum, dyspnœa, and venous engorgement, will enable a tentative diagnosis of the condition to be made. In our own case the diagnosis was rendered difficult by the small size and limited central position of the neoplasm, and by the absence of any marked fullness of the veins. Probably, if the idea of the thymus as the possible seat of trouble had been present in our minds, it would have been considered as a possible explanation of the symptoms. The original diagnosis of tuberculosis of the lungs was rather a matter of convenience than an act of faith, but we find that the same initial error of judgment was made in a case reported by Brannan.[16] The stenosis of the trachea seen in the X ray plates never seemed adequate to explain the degree of dyspnœa from which the patient suffered, and indeed even at the necropsy there seemed a sufficiently wide lumen to the trachea to admit of quiet respiration. Possibly during life, when the parts were full of blood, the degree of narrowing was greater than it appeared post mortem; or perhaps more probably the growth was drawn into the upper aperture of the thorax at each inspiration and acted as a ball-valve, so as to impede the entrance of air. The patient was seen by many physicians during her stay in hospital, and the favourite diagnosis was that of adhesive mediastinitis, with consequent indrawing of the chest walls. The shrinkage of the lungs and consequent exposure of the heart behind the sternum were recognised clinically, but the extreme degree of fibrosis of the lungs was not suspected. Indeed, we do not remember to have seen in any other case so advanced a condition of bilateral fibrous induration and airlessness, or such extreme approximation of the anterior wall of the thorax to the vertebral column and back of the chest.

Treatment and Prognosis.

Lenz [17] records a case in which an epithelial tumour of the thymus was successfully removed by operation and the patient recovered. In our own case this would have been quite impossible, owing to the way in which the neoplasm had grown round the arterial stems, and a similar embedding of the great vessels was noted in the great majority of recorded cases. Instances are reported in which thymic tumours disappeared under treatment with radium or X rays, but in such cases it is impossible to be sure of the nature of the condition. Apart from such means of treatment, the outlook is, of course, hopeless, but the duration of life after the onset of symptoms varies very greatly. Kneringer and Priesel [18] record the case of an old man, aged 71, in whom the disease had apparently lasted for over eight years; on the other hand, a child of 9 years died in 26 days (Miller [19]). A duration of two years is not very rare, but the majority of patients die within a year of the onset of symptoms. In our own case the disease seems to have been present for "several years" before the girl came into hospital, and the tumour must have already attained a considerable size nearly two years before admission when she was conscious of a lump in her throat. It was clearly a slowly growing formation of low malignancy, as indicated by the dense hyaline fibrous stroma, the small amount of glandular infection, and the absence of any visible changes in the pulmonary metastases during the time she was under observation.

Our thanks are due to Prof. Kettle for his kind help and advice; also to Dr. E. E. Atkin, director of the pathological department at Brompton Hospital, for his trouble in preparing sections for examination and mounting the specimen.

THE INCIDENCE OF OSTEOMALACIA AND LATE RICKETS IN NORTHERN INDIA.

By Dagmar Curjel Wilson, M.D. Glasg.,
D.P.H. Camb.,
WOMEN'S MEDICAL SERVICE, INDIA (RETD.).

The inquiry of which the results are summarised in this paper was carried out under the Indian Research Fund Association.

The ætiology of osteomalacia has roused considerable interest during the last two decades. A survey of recent work [2] suggests that osteomalacia is a true deficiency disease and that its ætiology is the same as that of early and late rickets, the clinical differences being due to a different physiological condition of the bone.

Rickets and osteomalacia are rarely noted in India south of Bombay and Calcutta; the cases on which this report is based were drawn from urban and rural areas in northern India and Kashmir. Four hundred urban cases of late rickets and osteomalacia were kept under observation at special clinics in Lahore, Amritsar, and Simla. Occasional rural cases of rickets and of osteomalacia associated with maternity were seen personally or recorded by doctors and health visitors among village girls and women in the northern Indian plains. Cases were reported among Pathan women of the nomadic *powindah* tribe in the North-West Frontier province, and among Mohammedan women in Kashmir villages. A very high incidence of rickets and osteomalacia was found at all ages, in both sexes, among Hindu field workers in the hilly Kangra district, and a household survey was carried out in a village of this area. The survey of the incidence among children of school age (5-17 years) included observation of children in certain industrial areas as well as of over 2000 children attending school in towns and in country districts.

Table I. and Ia.—*Factors Influencing the Onset in 400 Cases of Late Rickets and Osteomalacia, from Clinics at Lahore, Amritsar, and Simla.*

Race.	M.	F.	Onset before union of epiphyses. Late rickets.		After Ep. U.*
			Age in years.	Cases.	
Hindu (Brahmin, Rajput, Kayasth, Jain, Khatri, Bania, Arora, Chumar, and Mehter)	5	204	5–10	33	
Mohammedan (Sayed, Punjabi, Hindustani (U.P.), Kashmiri) ..	1	150	10	18	
Sikh	—	29	11 12	14 25	
Indian Christian ..	—	11	13 14 15 16	29 34 32 41	
	6	394	—	226	174

* After Ep. U. = Onset over 17 years, after epiphyseal union osteomalacia.

Table Ia.

Relation of onset to marriage	Before	148
	After	252
Associated with pregnancy, lactation, or abortion		218
Associated with illness: fever, 4; pneumonia, 3; cholera, 2; intestina infection, 2; small-pox, 2; disability after accident, 2; measles, 1; abdominal tuberculosis, 1		17
Deficient	Sunlight (housing and purdah). (A familial incidence was observed in 100 cases where sun or diet were very deficient)	240
	Diet	160
Social condition of amily	Poor (coolies, menial workers)	209
	Fair (storekeepers, mechanics, clerks)	174
	Good (merchants, lawyers, officials)	17

Race, Sex, and Mode of Onset.—No race in northern India is immune, but rickets in its various forms—osteomalacia, late rickets, and infantile rickets—is more prevalent in certain castes owing to their mode of life. Under normal Indian conditions the men and boys of a family obtain adequate sunlight and the best of the available diet, so that rickets is rare among them except in conditions of extreme deficiency of diet or sun, as in the Kangra district and in carpet works at Amritsar. The disease is chiefly met with among girls and women during adolescence and maternity (marriage often takes place at the onset of puberty). The incidence of infantile rickets is fairly equally distributed between the sexes. In this series of cases it was rare for the children (all breast-fed) born of osteomalacic mothers to show clinical signs of rickets until their second year; one case of fœtal rickets was reported. The onset of late rickets and osteomalacia, which is often insidious and characterised by intermissions, was found to occur at any age from 5 to 54 years; many cases date from ten years upwards in association with adolescence and maternity (Table I.).

Lines of Investigation.

URBAN.

The housing conditions in crowded areas are such as afford scant opportunity for obtaining much sunlight, and the Indian girl or woman rarely ventures any distance from her home. Observations on the intensity of the ultra-violet solar radiation made by various observers, using Hill's acetone methylene-blue gauze in different Indian towns, give readings in units per day varying according to the season from 3 to 12. These readings are for exposure in the open; in the small dark room which is the poorer city woman's home the results of exposure are nil. Many urban Hindus have only small quantities of milk and fats, ghi (i.e., clarified butter) or vegetable oils, in their diet, which consists chiefly of cereals and cooked vegetables; they do not observe purdah, and derive such vitamin D as they get mainly from exposure to the sun. Mohammedan girls begin to observe purdah from 7 to 10 years of age onwards, and thenceforth have even less opportunity of obtaining vitamin D from the sun. Thus, although the diet of the Mohammedans contains some animal fat and is rather more balanced than that of the Hindus, their mode of living leads to even more deficiency in vitamin D. These diets usually contain an adequate amount of vitamin B, but an excess of cereal plays some part in rendering the condition of the patient worse.

A study of conditions in Ludhiana is instructive. In this town careful inquiry by doctors and health visitors over a period of two years could only disclose five indigenous cases of rickets and osteomalacia. It was found that the diet of the average household did not differ materially from that of women in Amritsar city, where the incidence is high, but in Ludhiana overcrowding was absent and each house received plentiful sunlight, which even those observing purdah could enjoy in open courtyards.

The constituents of the diet of 265 girls and women attending the special clinics were considered in detail, and their symptoms classified according to the degree of severity (Table II.).

Treatment consisted of the administration of some form of vitamin D (cod-liver oil containing that vitamin, or an irradiated substance such as Ostelin or Vigantol, for patients who disliked the use of animal oil), combined with the daily use of milk (not less than 8 ounces), fresh fruit or greens, and sunlight (at least two hours out of doors, with as much direct exposure of the skin as practicable), and massage of the affected parts.

TABLE II.—*Relation of Lack of Vitamin D to Severity of Clinical Symptoms.*

Diet.	Clinical symptoms.			Total cases (265).
	+++	++	+

II. Partial lack of vitamin D ..	14	70	71	155
III. Fairly adequately compensated for vitamins D, A, and C	3	2	15	20
IV. Border-line diets (with regard to vitamin content) ..	—	2	3	5

Of the patients treated, 244 attended the clinic regularly for six weeks, and the improvement in their condition was shown by diminution of pain and of muscular spasm with consequent lessening of deformity. Many cases were controlled by X ray examination. The remaining 21 cases did not return for treatment (Table III.).

II.	—	22	44	77	143
III.	—	—		19	20
IV.	—	—	—	5	5

Observations were made on the value of the different factors in treatment on 41 girls and women, cases of late rickets and osteomalacia of moderate or severe degree, and the results were controlled by repeated X ray examination. Patients continued to live in their own houses but attended the clinic regularly for at least three weeks, and many were kept under observation for two to five months. They were divided into five groups and treated respectively by the addition of (1) diet (milk and fruit), (2) sun (two hours' exposure daily), (3) vitamin D alone (full dose), (4) diet+sun, (5) sun+vitamin D. Each factor added was partaken of under supervision for a period of three weeks.

The results indicate the importance of food values and a balanced diet in treatment.

Group I., ten patients, all put on weight, although seven of them, who were very poor and living under most unfavourable conditions, had no lessening of pain or spasm. After the three weeks of observation were completed they very rapidly improved on the addition of vitamin D. The remaining three patients belonged socially to the middle class, lived amongst much more favourable surroundings, and were in the habit of obtaining sunlight; their symptoms improved so much that it was unnecessary later to supplement treatment with vitamin D.

Group II., five patients, all wives of industrial workers on small wages having a very unbalanced diet, showed no obvious improvement, but when, after three weeks' treatment, vitamin D was added, their symptoms cleared up slowly.

Group III., twelve patients, improved slowly under treatment.

Group IV., seven patients, improved slowly under treatment.

Group V., seven patients, improved under treatment considerably more rapidly than Group III.

Massage or galvanic baths are useful in easing pain; exercises are also helpful. Indirect ultra-violet irradiation can, if necessary, be substituted for exposure to sunlight. Experiments have been made with the use of Indian fish oils, and also attempts to get irradiated substances manufactured on a commercial scale in India, but so far unsuccessfully.

RURAL.

In the Kangra district the population in proportion to the cultivated area has reached a limit already exceeding the capacity of the country to support it. A household survey was carried on in a village called Launa (altitude 4300 feet). The inhabitants are field workers and accustomed to open-air life. Plentiful sunshine is available for eight months in the year; in the remaining four there are rains and mist, and during this period patients state that their pains are worse. Village families fall into three groups: chumars, the lowest social class in the village, in which the men and women are field workers on other people's land; zemindars, usually cultivating their own land; and Gurkhas, the families of military pensioners (Table IV.).

M.=male; F.=female.

The addition of vitamin D, together with milk and fruit, daily to the diet caused rapid improvement in the condition of 27 cases; it is, however, impossible for these patients to continue such diet on their own earnings (Table V.).

Since the Kangra district lies in the Himalayan tract, goitre is prevalent, but it does not occur more frequently among cases of rickets or osteomalacia, nor does their improvement on treatment cause any decrease in the goitre. Goitre is rarely present among urban or rural cases in the plains.

Summary.

A high incidence of rickets and osteomalacia was found in overcrowded cities and in towns with narrow lanes and high sunless houses, or in densely populated bazaars among Hindu and among purdah-observing Mohammedan women and girls. The diet of such patients was found to be deficient in vitamin D and in certain cases in vitamins A and C also. In rural areas, when diet is markedly deficient, adequate sunlight cannot prevent rickets or osteomalacia.

Investigation of the diet, housing, and customs of over 1500 cases of rickets and osteomalacia in northern India shows that a consistent lack of vitamin D in connexion with diet and lack of sunlight is an ætiological factor, thus confirming the experimental findings in various parts of the world. Improvement in diet causes but little improvement in symptoms if sunlight is deficient; conversely the provision of sunlight for cases on very deficient diet is of little use. The results of treatment show that cases on full doses of vitamin D improve gradually, but in order to get more rapid results it is advisable to combine the use of a moderate dose of vitamin D with daily exposure to sunlight and an improved diet (i.e., the addition of vitamins A and C). There is also much value in thus training patients in a better mode of life.

A grant-in-aid towards the cost of this inquiry was received from the Punjab Government. Throughout the inquiry much helpful criticism was received from Surgeon-General J. W. D. Megaw. I also wish to express my indebtedness to the following collaborators: Ella Surie, M.Sc. Lond., with regard to dietary factors in the ætiology of osteomalacia, and also a preliminary inquiry on the incidence of rickets and dental caries in India; Gulbai P. Patel, M.B. Lond., with regard to the blood-picture; and W. K. Coombes, M.R.C.S. Eng., with regard to the radiological examinations in connexion with factors in treatment. An X ray study of osteomalacia was undertaken independently by V. E. Pilley.[1]

ACUTE ASEPTIC MENINGITIS.

By John Gibbens, M.B. Camb., M.R.C.P. Lond.,
CHIEF ASSISTANT IN THE CHILDREN'S DEPARTMENT, ST. THOMAS'S HOSPITAL; PHYSICIAN IN CHARGE OF CHILDREN, ST. JOHN'S HOSPITAL, LEWISHAM.

At the present time there are appearing throughout the world an increased number of unusual, little understood, infections of the central nervous system, such as post-vaccinal encephalitis and diffuse encephalomyelitis. In view of this we should like to call attention to another type of case which is apparently becoming commoner in this country and which has recently appeared in small epidemics on the Continent, especially in Germany and Scandinavia. It closely resembles tuberculous meningitis—in fact, this is the diagnosis confidently made in practically every case—and since the prognosis is absolutely good, the differential diagnosis is obviously of great importance.

Nomenclature.

The cases show an extraordinarily similar onset and course, and this is one of the main features of this disease which we have termed "acute aseptic meningitis." It is not a new disease. Cases of this type have long been known and described under various terms—benign aseptic purulent meningitis (Schiff[1]), acute idiopathic benign serous meningitis (Andersen and Wulff[2]), epidemic meningitis serosa (Eckstein[3]), acute aseptic meningitis (Gunther[4]), &c. In the absence of more definite knowledge this last name seems the best. At present it is not known if all the cases have a similar ætiology; it is possible, even probable, in spite of the uniformity of the clinical picture, that they have not.

The cases are called "aseptic meningitis," since no organisms have yet been found in the cerebro-spinal fluid. The "serous meningitis," so well-known to otologists, at first sight seems to be something of the same nature—the early stage of a definite meningitis due either to some organisms of low virulence or to organisms as yet remote from the meninges. The increase in cells and protein indicates that the inflammatory process is just reaching the subarachnoid space: in the serous meningitis complicating otitis media these cells are lymphocytes at first, to be superseded by polymorphs later when the inflammation is extending. The onset is subacute, and the clinical picture reaches its climax slowly; then the signs either slowly disappear or a frank meningitis gradually develops. It is easy to visualise here the gradual invasion of the meninges by pyogenic organisms, a mild pyogenic meningitis which the body overcomes. In aseptic meningitis, however, we are faced with a dilemma; the uniformly abrupt, even fulminating, onset, and the severity of the clinical picture seem to indicate an infecting organism of high virulence, yet the short course and rapid regular recovery and the absence of any known organisms in the cerebro-spinal fluid are all against this. The change during the course of the disease from a predominance of lymphocytes to polymorphs in the cerebro-spinal fluid never occurs in aseptic meningitis: either lymphocytes are found in excess throughout the whole illness, or polymorphs predominate at first and there is a lymphocytic predominance later.

Acute aseptic meningitis has the following characteristics for its definition:—

1. An acute onset with definite meningeal signs.
2. Meningeal changes in the cerebro-spinal fluid; there is an increase of pressure and of cells—but the fluid is sterile on culture.

3. A uniform clinical symptomatology.
4. A relatively short benign course without secondary complications.
5. No epidemiological connexion with any known infectious meningeal disease.
6. There is no local infection, such as otitis media or sinusitis.

History.

Sporadic cases answering to the above definition have long been known, and it is highly probable that many of the cases published as healed tuberculous meningitis are of this type. The records of many of these cases are now too old or too incomplete to be of much value.

In 1910 a small series of 14 cases were reported in Paris under various names: Laubry and Foy,[5] syndrome meningé avec lymphocytie rachidienne d'origine indeterminée (3 cases); Rist and Rolland,[6] méningite benigne d'allure épidémique (5 cases). These cases were absolutely typical. At the same time Guillain and Richet[7] published four cases of benign lymphocytic meningitis complicated with jaundice; and Rist[8] showed that many cases of benign infectious jaundice were occurring simultaneously in the Paris hospitals. The jaundice was of the obstructive type—excess of bile in the serum and urine, and no bile in the stools—and the liver was slightly tender but not enlarged. This was accompanied by mild fever, severe headache, and a marked lymphocytic reaction in the cerebro-spinal fluid, but few signs in the central nervous system. Blood examination in one case showed a leucocytosis of 30,000, 93 per cent. of which were polymorphs. No jaundice, however, has been noticed in any case reported since 1910. These earlier case reports have been well reviewed recently by Roch, Martin, and Monedjikova,[9] and will not be dealt with here, since they present no unusual features.

From 1910 to 1925, little or no mention is made of acute aseptic meningitis, and then Wallgren,[10] in a paper entitled, A New Infectious Disease of the Central Nervous System, described a small Swedish epidemic of 19 cases. His cases also were typical.

Symptoms.

The onset is very acute with definite meningeal signs, the previous health being usually quite good; occasionally there is malaise for a few days, but as a rule there are no abnormal symptoms. Suddenly the patient becomes very ill, most children being so ill that they are thought to be in danger of their lives. The most common meningeal signs are headaches, which are severe and mostly occipital, vomiting, and stiff neck; pains in the neck and limbs are often severe, and there is intractable insomnia. Spinal signs are frequent: in bad cases there is marked rigidity of the back and stiffness of the neck, and the patient lies in a meningeal position; in the milder cases rigidity is only shown by a positive Kernig or Brudzinski's sign. The patient is extremely sensitive to movement and the reflexes are everywhere very active. Cerebral signs are much less marked; consciousness is usually not affected, and lethargy is never seen. There is marked dermographism. Convulsions are uncommon except in very young children. If the child is young enough, the fontanelle is found to be bulging. Teeth-grinding is often noted as a symptom. Eye signs are frequently found, the commonest being nystagmus, squint, and photophobia. Papillœdema has been noted in some cases, also hæmorrhage into the fundus (Eckstein[3]), and in some the pupils are unequal and react sluggishly to light. Apart from a facial palsy, which is rare, the cranial nerves are normal. Haessler, Eckstein, and others emphasise the fact that most of the children have sore-throat or severe nasopharyngitis, from which hæmolytic streptococci can be cultured. Some have ulcerative stomatitis.

The abdomen is usually retracted, with active reflexes, and there is no enlargement of the spleen or liver; constipation is the rule. No physical signs are found in the respiratory tract. Some authors mention a slow pulse, but this is not constant.

At the onset *fever* is usually high, continuous, or remittent, while a few of the reported cases are subfebrile. The duration of fever is short—from 3–13 days, averaging seven days. In the rapid cases it falls by lysis after the first few days, while in the stormy cases, after the fall, there may be a recurrence of intermittent fever for a few days.

Cerebro-spinal Fluid.

On lumbar puncture the cerebro-spinal fluid is found under pressure, sometimes markedly increased. The fluid is clear or sometimes cloudy; in a few cases reported it was purulent. In three of Eckstein's cases there was a definite spider-web clot. The cells vary in number, from 60 to a maximum of 1500 being reported; the average case shows about 100–250 cells. These are mainly lymphocytes, but at the onset of the disease polymorphs may predominate, to be replaced by lymphocytes later, this change often being quite rapid. In one case of Laubry and Foy the cells in the cerebro-spinal fluid were as follows:—

		Per cent.		Per cent.
March 17th ..	Polymorphs	95 ..	Lymphocytes ..	5
,, 18th ..	,,	90 ..	,,	10
,, 20th ..	,,	35 ..	,,	65
,, 23rd ..	,,	10 ..	,,	90

A typical case illustrating this transition is reported by Schiff.[1]

Baby of 11 months, admitted on March 28th comatose, with fever, bulging of the fontanelle, and a marked stiff neck. Kernig's sign was positive and both plantar responses were extensor. Pirquet test positive. Pupils and cranial nerves normal. Marked dermographia; retracted abdomen. Urine normal. Blood count: 16,000 leucocytes, of which 41 per cent. were lymphocytes, 50 per cent. polymorphs, and 7 per cent. monocytes. Lumbar puncture produced purulent fluid under pressure; numerous polymorphs, but very few lymphocytes. No clot; no tubercle bacilli; no organisms seen or cultured. Protein++. "Sugar reaction" negative.

April 1st: Clinical condition unchanged but now more lymphocytes than polymorphs in the cerebro-spinal fluid. 3rd: Temperature 103°. Stiff neck more marked; restless, sleepy, and rolling the eyes about.

April 8th: Well and playing in bed. No signs of disease in the nervous system; cerebro-spinal fluid clear.

April 21st: No increase of cells in the cerebro-spinal fluid. Examined three years later, entirely normal.

In Andersen and Wulff's cases[2] reported from Denmark, 27 cases showed exclusively or mainly lymphocytes; in two cases there were an equal number of lymphocytes and polymorphs and in three cases polymorphs predominated, the actual counts being 150/3, 3100/3, 165/3. In the last case the cerebro-spinal fluid later in the course of the disease showed mainly lymphocytes, the actual figure being 1500/3. (Andersen and Wulff consider that these last cases must be considered as acute aseptic meningitis since the clinical course was entirely similar. I shall refer to this later in dealing with differential diagnosis.)

The protein in the cerebro-spinal fluid is increased, Pandy's reaction being always positive. The sugar content is normal, varying from 0·03 to 0·06 per cent. The cerebro-spinal fluid, cultured aerobically and anaerobically many times by different observers, has always been sterile; no tubercle bacilli are found, and guinea-pig tests have always been negative.

CLINICAL AND LABORATORY NOTES

ARTERIAL THROMBOSIS ASSOCIATED WITH NEUROFIBROMATOSIS OF THE LUMBAR SYMPATHETIC CORD.

BY E. D. TELFORD, F.R.C.S. ENG.,
PROFESSOR OF SYSTEMATIC SURGERY, UNIVERSITY OF MANCHESTER;

AND

J. S. B. STOPFORD, M.D. MANCH., F.R.S.,
PROFESSOR OF ANATOMY IN THE UNIVERSITY.

THE condition of thrombo-angeiitis obliterans has of recent years become more generally recognised and the literature of the subject is already considerable. In spite however of an increased knowledge of the clinical features of the disease we seem unfortunately no nearer to a solution of its ætiology. Racial pecularity, tobacco, cold, and hyperadrenalinæmia have each been invoked as a cause, but so far without conviction. We desire to place on record a case of extensive arterial thrombosis of the lower limbs in which a very definite and possibly causal lesion was found at operation on the lumbar sympathetic cord.

FIRST ADMISSION: AMPUTATION.

X. Y., male, 43 years, British born, an engineer's fitter, was admitted to the Manchester Royal Infirmary in February of this year. He stated that two years before admission he had noticed difficulty in walking and was obliged to rest after walking about 200 yards owing to severe pain in the calf of the left leg. The condition got steadily worse and within a short time began to develop in the right leg. For some weeks before admission he had been confined to bed and had suffered greatly from continuous severe pain and loss of sleep.

On admission, the left lower extremity showed gangrene of the great toe and a large patch of gangrene on the dorsum of the foot involving also the fourth and fifth toes. The circulatory condition of the limb was very grave; no pulsation could be obtained below the common femoral artery at Poupart's ligament. The right leg was also seriously involved but showed no actual gangrene; a slight pulse could be felt in the superficial femoral artery on this side.

The man's general condition was critical; he was weak, emaciated, and in a state of constant rambling delirium, due no doubt to septic absorption and want of sleep. The case appeared to present the clinical features of thrombo-angeiitis obliterans of a somewhat rapid course.

Investigation of the patient showed that the Wassermann reaction was negative, the coagulation time of the blood was one and three-quarter minutes, and the blood calcium registered 10 mg. per 100 c.cm. The patient had always worked under cover and he was stated to have been a hard-working and steady man with no previous illness; his consumption of tobacco was about 20 cigarettes daily.

It was obvious from his condition that the only treatment possible was a supracondylar amputation of the thigh and this was done at once. The operation was followed by a prompt recovery, the delirium disappeared, his general condition improved, and he was discharged at the end of a fortnight with a well-healed stump.

A very complete dissection of the arteries of the amputated limb was made and many sections of all the named arteries and several smaller vessels were examined. All showed obliteration by well-organised and partially canalised fibrous tissue with the exception of the anterior tibial artery, in which the lumen was patent and but slight changes visible in the wall.

SECOND ADMISSION: LUMBAR SYMPATHECTOMY.

Early in April some six weeks after his discharge he was readmitted with gangrene of two toes and the heel of the right foot. It was decided to try the effect of lumbar sympathectomy and this was done on April 25th. Under spinal anæsthesia the right lumbar sympathetic cord was exposed by the retro-peritoneal route. Overlying the sympathetic cord was a chain of slightly enlarged lymphatic glands and on removal of these the cord was found to be very greatly thickened. The second lumbar ramus was identified and above this point the cord appeared normal. On tracing the cord downwards, the thickening was found to extend to the lower border of the common iliac artery where it broke up into perfectly normal branches. The whole cord from above the second lumbar ramus to its point of division into pelvic branches was removed.

A striking and immediate effect of the operation was the complete relief of the severe pain from which the man had suffered, and this relief of pain has so far been complete and permanent. Within 24 hours it was evident that the condition of the limb had improved; it was warmer, and the skin exhibited a better colour. The gangrenous areas also began to heal and within six weeks the large slough of the heel had been cast off, leaving a healthy granulating surface. A line of demarcation formed at the base of the two gangrenous toes, which are now rapidly undergoing spontaneous separation. The man has recovered his normal mental and physicial condition; he has required no anodynes since the night of operation, whereas before operation he was constantly under the influence of morphia.

THE EXCISED CORD.

An examination of the excised lumbar sympathetic cord shows the following features: the thickening of the cord was quite uniform and no nodular enlargements or irregularies were present. The transverse diameter throughout the affected portion was increased to some six times the normal size.

Sections were cut and stained with hæmalum and eosin, Mallory's connective tissue stain, toluidin blue, and van Gieson's stain. Microscopic examination at once revealed the fact that the enlargement of the cord was due to a great increase in the amount of supporting tissue. The nerve-cells stained normally and appeared to be perfectly healthy; they were scattered somewhat diffusely, as is not uncommon in this part of the sympathetic cord, but the cells were separated from one another more widely than usual owing to the increase in the amount of connective tissue around them. Large numbers of healthy nerve-fibres were to be seen and these were surrounded individually, or in small groups, by a dense fibrous tissue. It was significant to observe that the overgrowth of fibrous tissue was obviously more pronounced in the neighbourhood of nerve-fibres than it was around the nerve-cells. It was, however, in both situations excessive in amount and definitely more dense than normal. A careful investigation by suitable staining methods was made by Dr. E. R. A. Cooper with the object of discovering whether any trace of neuroglia was present, but none was found after a prolonged search.

The histological picture may be summed up as one typical of neurofibromatosis and the appearances suggested that the fibrous infiltration of the cord was capable of inducing irritation of the nerve-fibres.

An examination of the excised lymphatic glands showed that their enlargement was due to an old-standing quiescent tuberculosis infection; their condition appeared to bear no relation to the changes found in the sympathetic cord.

Comment.

The findings in this case raise several points of interest. In the first place the sections of the arteries from the amputated left leg showed changes closely resembling those which have been described by Buerger [1] and seen by us [2] as characteristics of thrombo-angeiitis obliterans. There are, however, despite a superficial resemblance, some points of difference. The most striking of these is the absence of fibrosis around the vessels or of any thickening of the adventitia. Thickening of the intima and great increase of elastic tissue were commonly found; these features were distinctly more pronounced than we have ever observed in cases of undoubted thrombo-angeiitis obliterans. The typical collections of lymphocytes during the organisation of thrombi were not found, nor were any giant cells seen. Marked fibrosis of the tunica media was almost a constant feature, but no evidence of lymphocytic infiltration was found.

The second point of interest is the association of neurofibromatosis of the lumbar sympathetic cord with the vascular changes in the domain of the vaso-constrictor fibres which reside in that part of the sympathetic system. The histological picture suggested strongly that these sympathetic fibres were subjected to irritation by the fibrous tissue around them. In previous papers[3 4] we have submitted evidence which indicates that sustained irritation of vasoconstrictor fibres can produce vascular changes, and in the more recent communication we have suggested a theory as to how these changes may be induced. It seems reasonable to state that we have in this case which we now report another example of the same process, though of a different form from any we have yet reported.

A third feature worthy of comment is the immediate disappearance of pain after excision of the sympathetic cord. This relief of pain has been noted by other observers and it seems that one may confidently expect it after this operation. The cessation of pain might, at first sight, be interpreted as indicating the division by the operation of sensory fibres from the diseased blood-vessels, but there are a number of reasons which render such explanation quite untenable. We submit that it is a direct result of the vasodilatation which ensures that some substance is flushed out of the tissue spaces. We agree with the view recently expressed by Sir Thomas Lewis in his St. Cyres Lecture[5] that the primary cause of the pain is the accumulation in the tissue spaces of some substance which cannot be removed by the impaired circulation.

During the last six years we have been able to study closely some 40 cases of thrombo-angeiitis obliterans and we have found in no case evidence of a nervous lesion associated in a causal relationship to the disease. It is obvious that no definite deduction can safely be made from an isolated case, but it is possible that, although this patient presented many features which would appear typical of thrombo-angeiitis obliterans, we may in reality be dealing with an undescribed disease closely resembling thrombo-angeiitis obliterans but dependent upon a different and hitherto unsuspected cause.

We place the case on record, therefore, in the hope that it may stimulate further inquiry on these lines. We suggest that the operation of excision of the lumbar sympathetic cord should be practised more frequently in cases of thrombo-angeiitis obliterans. It seems probable that it may save amputation or at least considerably lower the level of amputation. Since it is clear that the beneficial result of the operation must depend upon the number of vessels which are still sufficiently unaffected to be able to dilate, the intervention should be done at as early a date as possible, preferably before the onset of gangrene. We would, in the light of our findings in this case, urge a very complete histological examination of the excised cord.

A CASE OF DUPUYTREN'S CONTRACTURE.

BY W. A. TRUMPER, M.R.C.S. ENG.

IN June, 1930, I was consulted by a single woman of 65 on account of the condition of her right hand. The ring finger was bent so much that the tip was level with the base and the little finger was flexed to about half this extent, the other fingers being normal. Neither of the affected fingers could be straightened, and two small tender nodules could be felt beneath the skin to the ulnar side of the middle of the palm. The patient attributed her condition to the use of a chopper in cutting wood. It was a typical Dupuytren's contracture.

Wishing to try the effect of local treatment before advising operation, I prescribed a thorough inunction of the palm twice daily with ung. iodi. denigrescens. After about 10 days the treatment had to be suspended on account of a local dermatitis of the palm with the formation of blisters. Movement was already returning in the affected fingers, and, after a second course of inunction, which also resulted in blisters, they could be fully extended. The nodules in the palm had also nearly disappeared, but the grip, however, was weak, and when flexing all the fingers to form a fist, the tips would not quite touch the hand. Subsequent exercises have rendered the hand quite useful, and in appearance perfectly normal. The patient states that she still notices a slight weakness of grip when wringing clothes.

It seems to me doubtful whether the improvement noted in this case was due to the iodine absorbed, or to the hyperæmia which accompanied the dermatitis. In either case it suggests a possible method of treatment for a troublesome condition.

Ivybridge, S. Devon.

METASTATIC DEPOSITS IN PRIMARY ADENOCARCINOMA OF THE SINUS PYRIFORMIS.

BY J. DURLABH DHRUV, F.R.C.S. ENG., D.L.O.,
SURGEON TO THE JAMSHEDJI JIJIBHAI HOSPITAL, BOMBAY.

A NATIVE Christian male, aged 35, sought advice for hoarse voice and increasing difficulty in swallowing. A hard mass could be felt in the right anterior triangle of the neck, fixed to the deeper structures. On indirect laryngoscopic examination a fungating growth was visible on the right aryteno-epiglottidean fold extending over the sinus pyriformis, as well as on the inner surface of the mucosa lining the arytenoid cartilage.

The growth being inoperable, an antiseptic mouth-wash and anodynes were prescribed. The patient was steadily going down hill, and it was found he had lost power in one arm and leg on the same side. A blood Wassermann test was negative. He was placed on a course of iodides, for the hemiplegia was supposed to be due to cerebral thrombosis. He had no headache or vomiting, and was conscious. (The fundus was not examined.) He had no pulmonary symptoms. He slowly died of asthenia.

At autopsy the right occipital lobe of the brain was found to be infiltrated with a growth the size of a lemon, soft in consistency, and bluish in colour. A similar mass the size of a chestnut was found at the apex of the left lung. Microscopical examination of the larynx, brain, and lung (affected areas) showed adenocarcinomatous changes. The only explanation for the hemiplegia of gradual onset was a microscopic invasion of the fibres of the internal capsule by the forward extension of the occipital growth.

It is possible that distant metastasis from laryngeal carcinoma is more common than is supposed. These cases should be seen early, and a very extensive dissection should be carried out.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE.

SECTION OF OTOLOGY: SUMMER MEETING.

THE summer meeting of this section took place at Queen's College, Oxford, on June 26th and 27th, the President, Mr. ALEXANDER TWEEDIE, being in the chair.

Dr. W. T. HILLIER (Birmingham) read a paper, supported by a series of large water-colour drawings, on the

Lateral Line Sense-Organs of Fishes.

The term "lateral line" signified a row of organs of special sense extending from the head backwards along the sides of the body; it was found only in creatures which led an aquatic life—i.e., fishes and amphibians. Not all kinds of fish had a lateral line; for example, neither the herring nor the mackerel had. Some fishes, such as necturus and amblystanaæ, had three lines on each side. The lateral line could be regarded as a poor relation of the human labyrinth. The auditory labyrinth had all the interest of a machine designed to fulfil a certain group of purposes, and consisted of a standing part and a moving part. It consisted not only of special nerve-endings, but also of accessories which served to protect those end-organs and improve their efficiency. Buddenbrock had stated, and had related experiments which supported that view, that there existed a definite functional relationship between the semicircular canals and the sense-organs found in the skin of many aquatic animals; and that the lateral line organs served for the perception by the fish of streaming water. Whether a fish moved against the stream or stayed in one spot was determined by visual stimuli. The lateral line was only part of a system of lines of special sense-organs, known as the neuromast system, because the end-organs were shaped somewhat like a nipple; there was also a series of lines over the head. In fishes which had scales, the canals of the lateral line pierced the scales, and usually there was one sense-organ to each scale. The organs of the lateral line proper were supplied by the lateral branch of the vagus, but those on the head by other cranial nerves. There existed in fishes also an acustico-lateral system. The marks in the bones caused by the acustico-lateral or neuromast system could be found in some of the very earliest forms of fish. The row of markings of the lateral line extended in an unbroken sequence along the body, often to the tail, so that the line must not be regarded as a series of segmental organs; it seemed to be no more than a repetition of one type of structure. Discussing the subject in the light of Darwin's views expressed in the chapter on Domestication in "The Origin of Species," he said that the alternation of generations was not an occasional curiosity, but a regularly recurring event in the phylogeny of animals, and quoted a number of instances of it. The development of the lateral line had been well shown by Henry Wilson in his account of the embryology of the sea bass; Beard had studied the development of the lateral line in the trout. Dr. Hillier himself had never been able, in his successful sections, to trace the nerves going to or from sense-organs; the nerve strand appeared to be incorporated in the epithelial lining of the canal. The sense-organs seemed to be concerned with the reception and interpretation of vibrations conveyed by water, and in the case of the amphibiæ the skin grew over the sense-organs during the terrestrial part of their existence. The most important contribution on the subject, so far, was that of G. H. Parker, in 1905. Parker found little to support the view that the lateral line was concerned with equilibration, and it was much inferior in this respect to the eye or the ear. Dr. Hillier's own experiments had shown that the lateral line on the underside was the sensitive one to external stimuli.

The PRESIDENT asked whether any connexion had been traced between the innervation of the lateral line organ and that of the utricle.

Dr. MUIR EVANS (Lowestoft) said he had tried to find out more about the connexion of the lateral line with the central nervous organisation. Herrick had pointed out that the great size of the vagal lobes in goldfish and carp was due to the fact that the fish received the sensation from the palatal organ in the roof of the mouth, which was covered by taste buds. A valuable line of investigation was on the relation of the acoustic lobe.

Mr. H. M. MACNAUGHTON-JONES submitted, and demonstrated by a series of models, some new conceptions on the

Physiology of the Ear.

It was currently taught and believed, he said, that the manubrium moved inwards and pushed in the stapes. The latter was supposed to be possible only by the pushing in of the foramen rotundum. His view, which the working models supported, was that a wave striking the membrana tympani caused the manubrium to move outwards, the foramen rotundum was pressed inwards, and the manubrium drew the stapes outwards. He did not found his new conception on the models, but made the models to prove his belief. He emphasised the great importance of maintaining a certain degree of tension on the stapedius muscle; it was also important for hearing that the stapes should be movable, and that the malleus should be tense.

The PRESIDENT said he believed that the tympanic membrane acted only as a protector of the contents of the middle ear. The functional integrity of the stapes seemed to be important, but the other two ossicles he regarded as of little importance, otherwise how could such excellent hearing exist with total defect of the tympanic membrane and a tolerant middle ear? Barany had recently suggested that in conversation sound was essentially transmitted through the foramen ovale, the incursions of which were balanced by the excursions of the foramen rotundum. Recently it had been shown that for lower tone perception the functional integrity of the stapes was absolutely necessary. The chief route of higher tones was directly through the foramen rotundum.

Dr. LOWNDES YATES said that various theories were held as to the function of the ossicles, but presumably the elaboration of a joint between the incus and the malleus was not without good reason. A similar joint existed between stapes and incus. It seemed that sounds of very short wave-length must be physically absorbed by those joints, so that the sounds of higher pitch must get to the internal ear by some route other than by the membrane; the choice of route must be between the oval window and the round window. After removal of the ossicles and the tympanic membrane, the tuning-fork could still be heard, though lower notes did not come through so well. Hearing diminished pari passu with the onset and increase of fibrosis in the wound which had been made. The tensor tympani enabled the ear to rest, to cease listening when something was transpiring which the person did not want to hear.

Mr. ERIC WATSON-WILLIAMS agreed with the President that the ossicles and membrane had not much to do with hearing; and he pointed out that the argument advanced by Mr. Macnaughton-Jones rested partly on the assumption that the membrane was not elastic, whereas for the purpose it had to serve its elasticity was practically perfect, and it offered virtually no impediment to the transmission of waves of pressure.

Dr. E. A. PETERS read a paper on a case of

Cerebellar Abscess Drained Anteriorly to the Lateral Sinus.

The patient was a woman, aged 29, seen last April, who in 1917 had had a double mastoidectomy. There had been an intermittent discharge since then. For some months she had had headache which latterly had become more persistent; felt over the whole head, but chiefly in the occipital region. On the day of admission she vomited for the first time. The temperature was 99° F., pulse 116, urine, sp. gr. 1030, acid. Later the head was retracted and she had Kernig's sign and diminished abdominal reflex. Cholesteatoma with meningitis was diagnosed. At operation a large cholesteatomatous excavation was found in the petrous bone. The tegmen tympani was removed, and the temporo-sphenoidal lobe exposed by enlarging the wound upwards. On incising the dura mater the cerebrum bulged outwards but did not protrude. Infection of the labyrinth was negatived by the satisfactory condition of the cochlear nerve and the absence of nystagmus; therefore the other possible infecting area anterior to the lateral sinus was removed by a gouge. The underlying dura was found to be softened, and was readily divided, and a few ounces of pus escaped, indicating an intradural or superficial cerebellar abscess. The puncture was perfused daily, and b.i.p. dressing was applied during the first week, paraffin and flavine later. There had been no defined focal indication of cerebellar abscess. Dr. Peters stressed the value, in early acute cases, of packing off the infecting petrous bone from the dura mater with b.i.p. after performing mastoidectomy, with removal of the diseased areas of bone.

Dr. PETERS also read a paper on a

Test for Maximum Tuning-fork Hearing.

He said that tuning-forks still yielded very useful results in testing hearing, and the value of those results was increased if fractional representation was used, the nominator representing the observation time, while the denominator expressed the normal time in seconds. Jointly with Mr. R. Lake he had pointed out that an even pressure of 8 oz. eliminated the variations due to the amount of pressure. In a man aged 23 in the silence room the following standard results were obtained:—

Tuning-fork of 128 vibr.	Seconds.	Tuning-fork 256 vibr.	Seconds.
1. Applied to mastoid ..	27	1.	30
2. Tuning-fork on mastoid with tragus closing meatus	27	2.	55
3. Tuning-fork held half an inch from meatus	27	3.	95
4. Tuning-fork on tragus closing meatus	85	4.	95

At the Saturday session the subject of discussion was the

Physics of Sound and Physiology of Hearing.

This was merged with a general discussion on the questionaire on otosclerosis[1] issued by the Otosclerosis Committee of the Section.

Mr. F. C. ORMEROD, the hon. secretary of that committee, said that the committee was now chiefly concerned with the quantitative tests of hearing, using tuning-forks, the voice, the whisper, and mechanical devices. An initial and serious difficulty was the fact that no two tuning-forks, considered to be similar, behaved in the same way; different makes of fork gave different rates of decay of the vibrations. This necessitated getting into touch with the makers of tuning-forks; a series of meetings were held in London, and a good deal of work was done at Sheffield on the matter. Forks were now being made which would accord with the requirements enunciated in the first part of the report—namely, that the half-intensity period should be not less than three seconds and not greater than ten seconds. The National Physical Laboratory were not able to help with a formula based upon fork dimensions, their opinion being that the result must be reached by separate experiment. A mathematician in a Sheffield firm had promised to supply shortly tuning-forks which would come within the committee's requirements. Without this standard fork it was not possible to compare properly the results of different observers.

The committee had also gone into the question of audiometers, and a number of German and American machines had been tested. A large electrical firm in this country was working on an audiometer and hoped to turn out a reliable instrument at a reasonable cost. Audiography was also needed, and reliable charts could only be the outcome of reliable forks and audiometers. The work of the committee had extended over a long time because they were constantly encountering fresh difficulties.

Mr. HALL PIKE said that certain facts had recently become known to physiologists with regard to the mechanism of the cochlea—i.e., the phenomenon observed by Weaver and Bray—working in Princeton University. They had been engaged in assessing the impulses in the auditory nerve, working on the lines of Adrian's investigations in this country. They placed one electrode on the exposed auditory nerve, and another on a different part of the body—working with cats—and connected these to an amplifying system with a loud speaker placed in an adjoining room. They then exposed the ear to sounds of various pitches. They found that all the sounds up to 5000 vibrations per second were faithfully reproduced in the loud speaker in the next room. Adrian's work had shown that the impulses in nearly all sensory nerves were more or less the same, and there was no à-priori reason for supposing that the auditory nerve would behave in any other way. Weaver and Bray considered these electrical changes in the nerve to be true nerve impulses, and then criticised the resonance theory and Adrian's work. Adrian had now been over the ground again. He found it was true that if an electrode was placed on the nerve, the effect stated was produced, but in order to get the effect it was not essential to place the electrode on the nerve; a thread electrode could be laid on the cochlea, on the neighbouring bone, and on the external auditory meatus, without touching the nerve, and the same effects ensued. Adrian regarded these—as he called them—electrical variations as due to the microphonic action of the cochlea. That was not incompatible with the existence of vibrations of the basilar membrane, such as the resonance theory implied. The practical point was that attempts to assess the true impulse in the auditory nerve were, in mammals at any rate, unlikely to succeed, since the true impulse would always be swamped by these microphonic impulses.

---

[1] This questionaire alludes to five types of case in which otosclerosis might be present, and the questions, 159 in number, are ranged under the following heads: 1. Ætiology: (*a*) heredity, (*b*) puberty and menopause, (*c*) sex, (*d*) pregnancy, (*e*) other conditions. 2. Examination of the patient: (*a*) local, (*b*) general, (*c*) hearing tests. Treatment: (*a*) general treatment, (*b*) local treatment, (*c*) operative treatment. It was decided at this meeting not to include "secondary otosclerosis," and to proceed with the inquiry on the lines indicated.

The effect of the impulses depended on the vitality of the cochlea; if the circulation to that organ was shut off, or if the auditory nerve was cut, the impulses ceased. This phenomenon was regarded by Adrian as due to the concomitant destruction of the blood-supply. Otologists were looking for a graphic way of representing what the ear was doing.

Sir JAMES DUNDAS-GRANT thought one important point was the difference of action of the nerve when alive and when dead.

Mr. GRAHAM BROWN said the whole auditory apparatus approximated to a wireless receiver; indeed, an analogy could almost be drawn between a microphone and the cochlea, and the question could be regarded as one of pure physics. Presumably this line of testing would eventually be carried out in man.

Mr. E. WATSON-WILLIAMS related a case in which, during a radical mastoid operation, when granulations were being picked out, the stapes was discharged with a little fluid. Two days later the patient had slight nystagmus when turning her eyes to the side opposite to the operation, but at that time there was no vestibular disturbance. She had, however, all the tuning-fork symptoms of ear deafness, and the Weber response was referred to the operated ear—i.e., she had no nerve deafness, though her labyrinth had been opened.

THE ORGAN OF CORTI.

Referring to otosclerosis, he said the terms generally used in discussing deafness were misleading. Too commonly, mention was made of inner-ear deafness without stating whether a lesion of the scala tympani or of the organ of Corti was meant. The true line of distinction between one type of deafness and the other was the organ of Corti itself. If there was no actual damage to the organ of Corti, the deafness was a conduction deafness; and it helped matters considerably if otologists drew the line of deafness not between middle ear and inner ear, but between ear deafness and nerve deafness.

The PRESIDENT said that the scala tympani and the scala vestibuli must be considered as the conducting medium. At one time there was a dictum at the Vienna school that if the stapes were displaced the fatal result was so certain that it was right to do a vestibulotomy, but Mr. Watson-Williams's case showed that this was not always necessary.

Sir JAMES DUNDAS-GRANT reminded the meeting of a paper he read some years ago showing a method of audiometry by tuning-forks, correcting the time error by a logarithmic scale, and reducing it to true loss of hearing power. That, however, accounted only for duration, not for the dying away of the vibrations. In discussing the physiology of the ear, he thought too little attention was paid to the importance of the fenestra rotunda; in his opinion this was the way by which high-pitched tones reached the labyrinth. The tones impinged where they were most likely to stimulate the basal fibres. For the transmission of deep tones he thought the tympanic mechanism was best suited.

SECTION OF UROLOGY.

AT a meeting of this section held on June 25th, the chair was taken by the President, Mr. S. G. MACDONALD, and Mr. OGIER WARD opened a discussion on the treatment of

Inoperable Carcinoma of the Bladder.

He said that the word "inoperable" was commonly used to describe cases which could not be cured by surgical removal of a growth—usually cases with wide extensions or secondary deposits, or in patients too weak for radical procedures. The chances of cure in cancer of the bladder were particularly difficult to estimate, and an exploratory examination was not generally useful; the decision had to rest on cystoscopy and bimanual examination. Fortunately the determination was not of the same importance in cancer of the bladder as in cancer of many other organs, because operative excision of the primary growth in squamous-celled, ulcerative, and nodular infiltrating types was the best treatment if it was at all possible, whether it cured or not. Therefore "inoperable" as applied to bladder growths meant only those which were fixed. Provided the cystoscope revealed any useful margin of healthful mucosa round the neoplasm, and provided the patient was fit, excision was useful for relief if for nothing else. Under this definition radium would obviously only be used in cases where there were considerable indeterminate extensions, and cure was very unlikely. Only too often radium produced large, chronic ulcers accompanied by severe cystitis. Radium might, however, arrest hæmorrhage and reduce suffering if the urine were kept sharply acid. Mr. Ward had treated 43 cases by radium between 1927 and the end of 1930; 15 of these had been treated by radium and open operation and 12 were dead. A further 11 did not live more than 12 months, but 3 had benefited to some extent.

RADON SEEDS.

The radon seed method, though of limited application and manifest imperfections, had some practical value. A flushing cystoscope must first be used, and the seeds could be inserted through the cystoscope, which afforded very accurate control of their deposition. Misplaced seeds were usually voided within 48 hours. Mr. Ward had used this method in eight cases which were beyond all possibility of excision; three had benefited, and one even appeared to be cured. The seeds were 6·0 by 1·1 mm. in size; their average strength was 1·3 to 1·7 millicuries, and 10 or 12 seeds on an average could be implanted at a time. Usually Mr. Ward did not combine diathermy with radium, though sometimes diathermy was used to destroy a cauliflower type of growth or to reduce hæmorrhage. Of nine cases of villous carcinoma treated with radon seeds, seven had had previous diathermy and five appeared to be cured. Two cases of "bald" carcinoma had been treated with seeds and in one the treatment had been at any rate temporarily successful. Nine cases of papilloma had been treated with seeds and cure appeared to be possible in four of them. Two more had undoubtedly benefited. Diathermy had proved of great value in these cases. These methods had the advantage that it was not necessary to open the bladder. Cystotomy was only useful to prevent attacks of clot retention.

SECTION OF NERVE TRACTS.

The terribly severe pain might be relieved by nerve section; the simplest method was the operation practised by G. Cotte of Lyons—the division of the presacral nerves on the fifth lumbar vertebra. Mr. Ward quoted a case he had seen at Prof. von Lichtenberg's clinic in which constant pain radiating down both sciatic nerves in an advanced infiltrating case of prostatic carcinoma had been entirely relieved by this operation. Mr. Ward had performed the operation three times during the last month. Any difficulty encountered was chiefly due to extraperitoneal fat or to the proximity of the inferior mesenteric vessels. All three patients had been considerably relieved. Pain could also be mitigated by chordotomy; laminectomy over the ninth dorsal segment and division of the antero-lateral tracts along a Stebbing's director. This operation was more severe, but its effect was certain.

Mr. **Kenneth Walker** said that inoperable carcinoma of the bladder presented a very difficult problem. Any measure of relief must be adopted to mitigate the frightful suffering. In his hands radium needles had had deplorable results; it was not easy to keep the urine acid, and ulceration with incrustation made the patient's remaining weeks worse than they would otherwise be. Division of the sacral nerves was a method worth pursuing. He had seen chordotomy give immediate relief to excruciating and intractable pain, but it was a separate procedure; what was needed was some method that could be carried out forthwith, as soon as the bladder surgeon found an inoperable growth. Presacral nerve section could not be as certain in its results as chordotomy, for in some cases the pain might be due to extensions. Presumably nerve section would be suitable for cases where the pain was associated with micturition only and was not continuous.

IMPLANTATION OF THE URETERS.

Mr. **Frank Kidd** thought that the pain was more often due to spasm of the bladder wall than to direct pressure, and that presacral division probably acted by relieving tension. In his opinion real progress would be made along the lines of speedy implantation of the ureters into the rectum with total extirpation of the bladder. This relieved pain more satisfactorily than any other method and each step alone was not very dangerous, though the procedure was extremely risky if both steps were performed at one sitting.

Mr. **Cyril Nitch** said that he had transplanted the ureters in 14 patients, seven of them cases of inoperable malignant growth of the bladder. All these seven had died, and all the non-malignant cases had recovered. The objection to the procedure was that in almost all carcinoma cases one or both ureters were thickened; the periureteral lymphatics were presumably infected and very likely the kidneys as well. He concluded, therefore, that transplantation of the ureters was practically hopeless at the present day for severe cases, though in milder cases it might be useful in order to afford relief when no other procedure was justifiable.

TWO TYPES OF GROWTH.

Mr. E. W. **Riches** recognised two main types of growth: the epitheliomatous ulcer and the more common hypertrophic—papillary or nodular—formation. The former gave rise to earlier metastases, while the latter might long remain a local growth. The prognosis and treatment were different in the two types. For the papillary type the best treatment was local excision by a cutting current followed by regular and persistent diathermy per urethram; this type was also perhaps more amenable to radium. The repeat treatments should be carried out under general anæsthesia every few months, and in many cases the growth could be kept under control. Radium inserted from inside the bladder had invariably caused a large slough in his cases, but had nevertheless given relief. Deep X ray therapy had not been successful but might be of value where there was lymphatic involvement. Permanent cystotomy did not give relief. The patient was given a better chance if the bladder were opened, because large masses of papilloma might be removed and also because the cystoscopic diagnosis of inoperability was so uncertain.

Mr. J. P. **Ross** thought that presacral nerve division was better than chordotomy because it would relieve pain without interfering with sensation in the lower part of the body. Though chordotomy was more certain, it should be reserved for a final measure.

DIATHERMY.

Mr. **Jocelyn Swan** believed that the surgeon could do much more for the papillary type of growth by extensive diathermy through a suprapubic opening than with radium. Astonishingly good results were obtained in the relief of pain. He had reserved radium for epitheliomatous growths, but had not obtained very satisfactory results. In his earlier cases he had perhaps used too heavy doses, and the result had been extensive sloughing which had greatly increased the patient's suffering. Radon seeds might be useful for growths which were inoperable by reason of position rather than of size. He preferred to insert them suprapubically, as the open incision allowed more even deposition than cystoscopic insertion. Transplantation of the ureters had in his hands given marked relief, but the great fallacy in this procedure was that in inoperable carcinoma of the bladder one or both kidneys were nearly always infected. Permanent suprapubic drainage and deep X ray therapy had given no relief at all, and so far the radium bomb had not proved any better. Glandular spread did not respond to radium. In his opinion, hope for these cases lay in diathermy for the papillary form and small doses of radium, inserted suprapubically, for the epitheliomatous form.

REPLY.

Mr. **Ward**, in reply, emphasised again the striking case he had seen in Prof. von Lichtenberg's clinic in which bilateral sciatic pain had been relieved by presacral nerve division, and urged that this procedure was worth trying for all types of pain and not only for irritable bladder.

NATIONAL ASSOCIATION FOR THE PREVENTION OF TUBERCULOSIS.

CONFERENCE AT MARGATE, JUNE 25TH–27TH.

THE seventeenth annual conference of the Association opened with a discussion on the

Protection of the Child from Tuberculosis,

the introductory address being given by Sir ROBERT PHILIP (Edinburgh), who urged the routine and systematic use of tuberculin to determine at the earliest possible moment the occurrence of tuberculous infection in the child. The test, repeated at intervals, was harmless and painless, while the knowledge obtained from it was priceless. As soon as a positive reaction appeared for the first time, nothing need be done while the child's health was maintained; but any failure of health would call for careful watching and the adoption of suitable measures. Only a minority of reactors would require individual treatment because of obvious disease, but since it was not easy to single out those who would develop disease, the knowledge afforded by a positive reaction at a given date would prove of supreme service in the interpretation of untoward symptoms and the adoption of suitable precautions. Sir Robert urged a closer coöperation between the department of maternity and child welfare and that of tuberculosis in relation to this problem of tuberculisation. If, he said, serious tuberculous illness of all kinds could be arrested under a simple sanatorium régime, it was no less possible, and was better policy, to stop the progress towards gross disease by ensuring that every nursery, every home, and every school should be run on the same physiological principles which formed the basis of sanatorium life.

Dr. EUGENE L. OPIE (Phipps Institute, Philadelphia) who followed dealt with the

VARYING MANIFESTATIONS

of tuberculosis at successive periods of childhood. A better understanding of the pathogenesis of tuberculosis and improved methods of recognising it had in recent years, he said, made three kinds of investigation notably profitable: (1) the search for tuberculosis in those who were apparently in good health (latent tuberculosis); (2) observation of the various forms of tuberculosis discoverable both in the sick and in the well, carried on over a period long enough to determine their ultimate outcome; and (3) reconsideration of factors involved in the transmission of the disease. Although the tuberculin test determined the presence or absence of tuberculous infection, the intensity of the reaction gave no widely applicable information as to the severity of the infection. Radiological examination defined with a fair degree of precision the anatomical characters, and measured the extent of the graver tuberculous lesions. Tuberculosis that had already undermined health and was recognisable by physical examination or by the discovery of tubercle bacilli in the sputum had by that time almost invariably produced advanced destructive changes in the lung. The examination of children living in contact with tuberculosis and the routine examination of school-children, had shown that grave pulmonary lesions could be discovered at a much earlier stage. The first of these two simple procedures had disclosed latent tuberculosis with such frequency that it was possible to follow up a considerable variety of lesions from their earliest stages until they developed into disease endangering life, or healed with the formation of fibrous or partially calcified scars.

The examination of school-children by means appropriate for the recognition of tuberculous infection offered, said Dr. Opie, the opportunity of measuring its frequency and severity in those who were believed to be in good health. Until the examination of presumably healthy children had been more widely applied, and those in whom lesions had been discovered had been observed through a period of years extending into early adult life, there could be no exact knowledge of their ultimate fate. Although most of the tuberculous infections of children as recalled by the tuberculin test produced focal lesions of lungs and lymph glands that became healed and calcified and caused no impairment of health, radiological examination of children well enough to attend school and of healthy children exposed to tuberculosis in their families had demonstrated the frequent occurrence of extensive infiltrating lesions of the lung parenchyma which, as subsequent observation showed, not infrequently developed into serious disease. Massive caseation of tracheo-bronchial lymph glands was recognisable only when well-defined, rounded, or oval masses could be seen in films at the hilum of the lung or on one side of the trachea. Such glands were of grave danger to life, especially in infancy and early childhood. With tuberculous infiltration of the childhood type there was diffuse opacity in X ray films, indicating tuberculous infiltration in some part of the lung field other than the apex. In one-third of the school-children in whom it was detected it was accompanied by inconspicuous symptoms and physical signs, and might be looked upon as clinically manifest, even though the children were believed to be well.

The adult type of pulmonary tuberculosis made its appearance during adolescence, and was, Dr. Opie said, a more serious lesion than the childhood type in younger children, being the precursor of much of the tuberculosis of early adult life.

Dr. LETITIA FAIRFIELD (County of London) dealt with the

Administrative Outlook

of tuberculosis in children under 16. The special difficulties of the public health officer in dealing with tuberculosis were, she said, partly due to the fact that it was both an overt disease of infancy and childhood causing death and disablement, and also a latent disease of childhood causing death and disablement only when adult life was reached. Administrative measures for infants and children up to the age of 5 years included mainly, provisions for the purity of the milk-supply, the protection of the infant from family infection, and the artificial immunisation of infants. The last of these, however, was not yet a practical proposition for English public health authorities in the light of present administrative experience. The general care and protection of the 2 to 5 age-group was admittedly a weak spot in public health administration. It affected the tuberculous child from the point of view of early detection of overt disease, heightening of resistance levels by attention to general health, and observation after the debilitating effects of the exanthemata. The difficulty was mainly a financial one, but the heavy "death and damage" rate of common ailments during these years should, the speaker thought, justify the expenditure of public money. The school period 5–15 showed a marked diminution of both pulmonary and non-pulmonary forms. Three important points were: (*a*) the necessity for more intensive and scientific research into the so-called "pre-tuberculous" group to disentangle those genuinely infected with tuberculosis from other similar physical types; (*b*) the value of energetic examination of contacts; (*c*) the coöperation of the tuberculosis service with school doctors. The necessity for vocational education should not be overlooked, in view of the importance of keeping children with arrested tuberculosis out of unsuitable trades or unskilled labour, where they would inevitably break down. Dr. Fairfield spoke of the probable value of raising the school age in enabling children to face the strain of industrial life in better conditions and in closing up the present gap in supervision between the school-leaving age of 14 and insurance at 16.

Protection at Various Ages.

Dr. **Reginald C. Jewesbury** considered the protection of the child from tuberculosis

AT BIRTH AND DURING EARLY YEARS.

Non-pulmonary tuberculosis was, he said, a common disease in the child, due to infection either by the humane or bovine type of bacillus. From the age of 1 to 5 years the tuberculous infection tended to attack the mesenteric and abdominal glands, the bones and joints, and the meninges. From 5 to 15 years it tended to attack chiefly the bronchial and mesenteric glands. Pulmonary tuberculosis in young children was rare, but when present it was serious. Infection from the bovine tubercle bacillus was definitely a preventable disease. Pasteurising or, better still, boiling the milk would make it safe for the child. In cases of infection from the human tubercle bacillus in the home, the risk could be minimised by careful training of the consumptive member of the family in the necessary hygienic precautions, the removal of an active and infectious case to a residential tuberculosis institution or proper isolation and nursing in the home or elsewhere, or, finally, by the removal of the child from the tuberculous home. Prophylactic vaccination by B C G had been applied in all European countries except England, Austria, and Portugal, but its use as an immunising agent, particularly for young children, could not be advocated until it could be shown to be free from virulence under all conditions and that it produced an effective immunity.

DURING PRE-SCHOOL YEARS.

Prof. **S. Lyle Cummins** (Cardiff) described the main problem as that of detecting the existence of active, though larval, tuberculosis, especially in the tracheobronchial lymphatic glands or in the form of early focal lesions of the lung tissue. Children harbouring lesions of this kind might, he said, appear to be in excellent health. There were two main aids to diagnosis: X ray examination and tuberculin tests. How to bring these tests to bear in a practical and economic way upon the children in infected homes was yet unsolved. Search should be made for new methods of detecting activity in latent or larval tuberculosis; such methods might be found, he said, in the application to young children of certain types of blood examination. Much more information was required as to the exact significance of tuberculin tests during the pre-school period of life, and arrangements should be made for the careful following-up of tested children during the subsequent years.

Dr. **T. R. Elliott** (Salop) suggested that the two chief requirements—(1) prevention of infection; (2) increasing individual resistance—could best be met by education in healthy living, in food values, and in the special food requirements of growing children, by better housing in general, and of infectious cases in particular, and by a more general use of open-air shelters for contacts; by occasional boarding-out of threatened children, and by the segregation of advanced cases. He outlined a scheme started in Shropshire in 1925 by which a pregnant woman suffering from pulmonary tuberculosis was sent to a sanatorium until her confinement was due, when she entered a nursing institution. As soon as the baby was born it was sent to a country home for ailing babies, where it was kept for 12 months under open-air conditions. Up to the present, none of the 33 babies thus dealt with had developed tuberculosis.

DURING SCHOOL AGE.

Dr. **R. H. Crowley** (Board of Education) said that although statistics had revealed the relative unimportance of the incidence of pulmonary tuberculosis at this stage of life, compared with earlier and later, yet even during the school period it was by no means negligible as a cause either of death or of disabling disease. In 1929 the death-rate in England and Wales from all forms of tuberculosis was 300 between 5 and 10 years, and 330 between 10 and 15 years, per million living; and the number of tuberculous children of school age in England and Wales on Dec. 31st, 1930, returned by school medical officers was 24,077. It was, he said, of primary importance to understand the significance of so-called latent tuberculosis, especially during early and mid-adolescence. Opie and others had made it probable that incipient tuberculosis of early adult life was advanced latent tuberculosis of adolescence. The surest method of protecting the child of school age was to remove a likely source of infection, or, failing that, to dilute it. Resistance to disease might be increased by providing midday meals, opportunity for rest, especially in the case of younger children, and facilities for playing and bathing. From the administrative point of view what was required was a medical service in the home linking up with the infant welfare and the school medical services.

Dr. **H. Midgley Turner** (Sheffield) said the main obstacle in the protection of children against serious tuberculous disease was the failure to realise that while sputum-positive pulmonary tuberculosis was rare among children, early pulmonary tuberculosis in the non-infectious stage was of frequent occurrence. There were sound reasons for believing that about half the serious tuberculous disease in young adult life owed its origin to childhood infection.

Dr. **L. S. T. Burrell** (London) said he doubted whether small infections acquired naturally gave real protection to the individual, and although experiments on the lines of immunisation were to be encouraged, he thought that endeavours to stamp out tuberculosis should centre round general hygiene. Any steps which were effective in making the individual more contented and free from worry, able to obtain good food, and to live under hygienic conditions, tended to stamp out tuberculosis.

EDINBURGH OBSTETRICAL SOCIETY.

Ureteric Lesions Causing Abdominal Pain.

A meeting of this society was held on June 10th with the President, Dr. **H. S. Davidson**, in the chair.

Dr. **Duncan M. Morison** read a paper on Ureteric

Lesions as a Cause of Abdominal Lesions: A Consideration of "Ureteritis" or "Ureteral Stricture"—a condition which had only been recognised comparatively recently as a clinical entity. The pathology was still obscure. As proved by corrective treatment many cases of apparently obscure abdominal pain were due to ureteric lesions. The zones of the ureter most frequently affected were the nodes or physiological sites of narrowing—i.e., (*a*) pelvo-ureteral junction, (*b*) where the ureter crossed the iliac vessels, (*c*) transvesical portion, (*d*) in women, where the ureter was associated with the broad ligament. Two types could be differentiated, congenital and acquired. The congenital type, due to some developmental error, was frequently characterised by a simple localised narrowing without any intramural thickening. The acquired form was apparently secondary to some primary focus of infection, such as tonsils, teeth, prostate, or cervix. It might also be induced by certain forms of repeated severe physical exertion—i.e., hammer throwing. The earlier phases of a ureteritis were associated with local hyperæsthesia of the overlying mucosa, any stimulus of which readily produced ureteral spasm. The initial stage of the infection did not give rise to any appreciable reduction of the ureteral lumen, but later, as intramural changes became more evident, localised zones of narrowing occurred at the sites affected. The intermittent attacks of spasm, and the more continuous impairment of the ureteral lumen, led to an increasing interference with urine conduction and the formation of stasis within the renal pelvis. Apart from the discomfort there was thus a progressive hindrance to renal elimination. As a general rule, low ureteritis would take longer to affect renal damage than would one situated at the pelvo-ureteral junction. The lumen of the ureter at the affected site rarely showed very marked reduction; hence the term ureteral stricture commonly applied was inaccurate except in a few instances where a definite fibrous stenosis was present. The use of this inappropriate term had led to misunderstanding of what was meant by this condition.

SYMPTOMATOLOGY.

The patient usually had a mild degree of toxæmia with lassitude, loss of mental acumen, headaches, nervousness, and irritability.

Local symptoms were attacks of vague pain in either kidney angle, or laterally below the costal margin, attended with nausea or sickness. It was probable that, in the presence of a ureteritis of the pelvo-ureteral junction, occasionally a dull ache was felt just below and lateral to the umbilicus. When the lesion was at the pelvic brim pains were referred to the inguinal region. Groin pains without bladder symptoms would point to a broad ligament source, while a suprapubic ache associated with attacks of urinary frequency usually indicated involvement of the ureter at or near its transvesical portion. If, as frequently occurred, a patient had more than one portion of the ureter affected, there was a corresponding grouping of these symptoms. The attacks of pain were commonly described as dull, persistent, and aching in character, frequently likened to a toothache. They might last from one to several hours. The pain was gradual in onset, reached a considerable degree of intensity then slowly subsided. At the period of intensity or most marked ureteral spasm there was very commonly a sense of renal discomfort indicating a damming back of urine on the renal pelvis. The pain was not induced by exercise, but fatigue or excessive exertion tended to bring it on. Patients frequently complained that they were awakened in the early hours of the morning with the pain, and that relief was only obtained by rising and walking about for a short time. It might be inferred from this that in the recumbent position the ureter was relatively more extended, and that the slight tension irritated the localised inflammatory area within the ureteral wall. There might be intermissions from pain for days, weeks, or months. Since a ureteritis favoured the formation of stasis in the higher urinary tract, chronic or relapsing pyelitis and calculus formation might occur as secondary conditions. It was essential that the primary contributing factor should not be overlooked.

DIAGNOSIS AND TREATMENT.

Since the symptoms might closely simulate those of the chronic appendix and disease in the pelvic organs, differential diagnosis was not easy. The absence of bladder symptoms in all but the transvesical lesion, together with a negative urine, tended to discount the possibility of any pathological condition of the urinary tract. A cystoscopic examination would fail to detect the lesion if ordinary straight ureteral catheters were employed unless the degree of ureteritis was sufficiently marked to render a stenosis evident. A positive diagnosis was based on the following findings: (*a*) the presence of residual urine in the renal pelvis; (*b*) calibration of the ureter by a "bulbed" bougie, noting mechanical resistance to the passage of the bulb or "hang" on its withdrawal, and the local induction of pain, and its character; (*c*) the presence following instrumentation of a reproduction or an exaggeration of the pain previously complained of.

Varying amounts of residual urine were to be found in the renal pelvis in cases of long standing or established ureteritis, but in the more recent types where ureteral drainage was still adequate there was usually none. In the earlier stages accordingly reliance had to be placed on calibration. By the employment of "bulbed" bougies the entire length of a ureter could be readily palpated and any altered zone detected. By a mechanical sense of touch combined with the statement of the patient regarding the site and character of pain produced, the location and type of a ureteritis might be determined. In doubtful cases, if the pain produced during or following the examination was not similar in character and location to the previously experienced pain, the ureter might be dismissed as a possible factor.

Treatment consisted in a course of progressive ureteral dilatation till a size of "bulb" bougie No. F.12 could be easily tolerated. By this means the attacks of pain were alleviated and, since better ureteral drainage was achieved, there was a corresponding removal of stasis within the renal pelvis with consequent benefit to general health.

Dr. J. R. CAMERON read a paper on Intracranial Injuries in the New-born, and their relations to Breech Delivery. He showed six dissected specimens of skulls from infants who had died either at or soon after breech delivery from intracranial injury. He described in detail the birth record of these cases, and suggested an association between the clinical management and the intracranial damage. The various anatomical factors involved in the production of these injuries was discussed.

Dr. W. P. KENNEDY gave records of a case of Streptococcal Infection of the Uterus Complicating Pregnancy.

REVIEWS AND NOTICES OF BOOKS

Pathology of Internal Diseases.

By WILLIAM BOYD, M.D., M.R.C.P. Edin., Dipl. Psych., F.R.C.S., Professor of Pathology in the University of Manitoba; Pathologist to the Winnipeg General Hospital. London: Henry Kimpton. 1931. Pp. 888. 45*s.*

THIS work is designed as a companion volume to Prof. Boyd's text-book of Surgical Pathology, published in 1925, and we predict for it an even greater success. There is need at present for a text-book of pathology suitable for the average physician. Many of those in general use are too large and too specialised to make an appeal outside the world of pathologists with the result that the physician tends to seek pathological information in the text-book of medicine. With this want in mind Prof. Boyd has endeavoured, with singular success, to act the part of the clinical teacher as well as the teacher of pathology, and to produce a book which will be suitable for the practising doctor and for those entering for higher examinations in medicine. His work deals with the special pathology of those diseases which are to be found in the medical wards of a general hospital. In order to avoid overlapping with his text-book of Surgical Pathology, the author has selected and pruned his material in such a way that certain matter which would find a place in a systematic text-book has been omitted. The omissions are of no great importance, however, and the book is comprehensive enough for practical purposes. Prof. Boyd takes the view that the chief purpose of pathology is to aid the physician in his work, and he discusses all problems in the light in which they occur to the clinician, making a special point of correlating the symptoms with the morbid anatomy of the disease. In order also to make the book as self-contained as possible, he has prefaced most of the sections with brief introductory notes on the anatomy, histology, and pathological physiology of the organ concerned. The reader whose activities have been remote from a medical school will have no difficulty in linking up the teaching in this work with his background of pathological knowledge. Much space is given to discussions of research and recent advances in pathology, and a useful list of references is appended to each section.

Prof. Boyd is not only a teacher possessing individuality and force but he is a writer of ability. He opens his work with the following words: "Of all the ailments which may blow out life's little candle, heart disease is the chief." Having stepped on this literary tight-rope he deftly maintains his poise to the last page. Since his book is not only readable but sound and up to date and clear, it should be popular with physicians and to those pathologists who retain some interest in clinical medicine.

Uber Physiologische Grundlagen bei der Ernährung Tuberkulöser.

By Prof. Dr. A. DURIG, Vorstand des Physiologischen Institutes in Wien. Vienna: Moritz Perles. Pp. 80. M.3.20.

Prof. Durig has written an interesting monograph dealing with the various aspects of metabolism and diet in relation to tuberculosis and has brought together a good deal of material which is not to be found in ordinary text-books. Beginning with mortality statistics of the war, when food conditions in all countries had an adverse effect on tuberculosis, especially in Central Europe, and continuing with the Charlottenburg figures on real wages and tuberculosis, the writer examines the many factors, anatomical, physiological, psychological, and pathological, which enter into this problem of metabolism and tuberculosis. Obviously, mere increase in adiposity does not necessarily add to the powers of natural resistance to tuberculous infection, and the time has gone by when doctors stuffed their patient ad nauseam. Account has to be taken of many factors not recognised by a previous generation of physicians. Prof. Durig includes in his survey most of these modern questions, such as the use of insulin, the vitamins, and the Gerson diet which has been so extensively tried out in Germany. A place is given also to more academic physiological topics, such as Pavlov's conditioned reflexes. The book is happily free from those long tables of caloric values of foods and the diagrams of intake and output which generally complicate this type of book; but it lacks also—and this we deplore—both a subject index and a bibliography, two very valuable adjuncts to a monograph which covers so many views and schools of thought. The use of chapter and sectional headings would also add to the convenience of the reader.

Organic Chemistry.

For Medical, Intermediate Science and Pharmaceutical Students. Second edition. By A. KILLEN MACBETH, M.A., D.Sc., F.I.C., Professor of Chemistry, Adelaide University. London: Longmans, Green and Co. 1931. Pp. 296. 6*s.* 8*d.*

THIS little book is intended to present the fundamental aspects of organic chemistry to the student in such a way that he may be encouraged to think more and memorise less; a very laudable object which the author's mode of presentation should go far to achieve. The difficulty encountered by the student on commencing organic chemistry is, in part, due to his inability to visualise the configuration of organic compounds; to overcome this difficulty the subject of configuration has been introduced at an earlier stage than is usual in many other text-books of this type, and there is much to be said for this arrangement. A further feature of the book is the attention paid to the more recent practical developments of applied organic chemistry such as the production of oil from coal, power alcohol, and synthetic methyl alcohol—to mention but a few examples. Such treatment of the subject is calculated to stimulate the imagination of the student and the book forms a good introduction to organic chemistry.

Creative Mind.

By C. SPEARMAN, Ph.D., Hon. LL.D., F.R.S., Foreign Member Société Française de Psychologie, Professor of Psychology at the University of London. London: Nisbet and Co., Ltd. 1930. Pp. 125. 5*s.*

Prof. Spearman has added considerably to the scientific development of psychology. Without his theoretical speculations, based upon many years of experimental and statistical research, experimental psychology as applied to education in particular would not stand where it does to-day. The mathematical psychology of correlation, coefficients, and tetrad difference may seem arid and disquieting topics, but in this book of singular charm and cultural breadth Prof. Spearman has extended his theory of cognition to the field of creative effort in art and scientific discovery. This theory of cognition is based upon the three laws of noegenesis, which state first that a person tends to know his own sensations, feelings, and strivings—a principle of apprehension; secondly, that "when two or more items are given, a person may perceive them to be in various ways related"; thirdly, "when an item and a relation to it are present to mind, then the mind can generate in itself another item so related." The somewhat abstract statements of qualitative and quantitative laws are illuminated by reference to pictorial and plastic art, and without detracting from the artistic merit of works of creative genius the author has certainly not given finality to æsthetic theory, but has established bonds between æsthetics and general psychology. Prof. Spearman always points out how scientific discovery pursues the same mental course as does artistic creativeness, and that everyday behaviour too is bound to these activities by the operation common to all three—the educing of correlates. Many will read these pages with a feeling that artistic creation, discovery, and behaviour need other factors for their explanation than the bare eduction of correlates, but no one will close the book without having had the experience of contact with a singularly penetrating intelligence.

Handbook of Protozoology.

By RICHARD ROKSABRO KUDO, D.Sc., Assistant Professor of Zoology, University of Illinois. London: Baillière, Tindall and Cox. 1931. Pp. 451. 25s.

UNLIKE other books on protozoology which have been published in recent years, this one deals very largely with free-living protozoa which numerically are a much larger group than parasitic forms. The parasitic protozoa are given only their fair share of the book without any special reference to their pathological importance. Thus the account of the hæmosporidia, including malarial parasites of man and animals and the piroplasmata, fills six pages, while the parasitic amœbæ and the trypanosomes and their allies are dealt with in 12 and 10 pages respectively. The book therefore is designed more for those who wish to study the protozoa as a group from the general zoological standpoint than for the parasitologist who requires detailed information about disease-producing forms. After a short introductory section follows an outline of classification indexed for reference to the succeeding systematic section which forms the bulk of the book. In this section each group is introduced by a short description, while definitions of orders, families, and genera follow with a brief mention of some of the more important species. Most of the text figures, and these are numerous, depict several organisms, in some cases a dozen or more, so that there is a wealth of illustration which greatly enhances the value of the book. The classification followed is the conventional one, the phylum protozoa being divided into two sub-phyla, plasmodroma and ciliophora, the former including the three classes mastigophora, sarcodina, and sporozoa, and the latter the two classes ciliata and suctoria. The subdivision of these classes agrees in the main with that found in other text-books. Of special interest are the sections devoted to the myxosporidia and the microsporidia, on both of which groups the author is a recognised authority.

The book will be of value not only to the zoologist, but also as a work of reference to medical men and parasitologists who in their dealings with pathogenic species are liable to encounter many non-parasitic forms. It may save them from many errors and will give them a picture of the protozoa as a whole in which the pathogenic forms appear in their true perspective. Prof. Kudo has produced an attractive handbook.

REPORTS AND ANALYSES

ENERGEN FOOD PRODUCTS.

(ENERGEN FOODS CO., LTD., ENERGEN WORKS, WILLESDEN.)

WE have received for examination a number of food materials prepared by this well-known firm. The underlying idea of all of them is to reduce the starch content and to raise the amount of assimilable protein or gluten. In this respect they will serve a useful purpose to those physicians who are concerned in prescribing diets to patients whose carbohydrate tolerance is low. For purposes of comparison the results are given in tabular form.

—	Nutrient pastry flour, rich in gluten.	Macaroni enriched with gluten.	Digestive biscuits.	Endobran biscuits.	Cocoa.
Price	1 lb. = 10*d.*	12 oz. = 1*s.* 6*d.*	½ lb. = 1*s.*	1 lb. = 3*s.* 6*d.*	Per carton = 1*s.* 3*d.*
Moisture (per cent.)	10·8	10·1	3·9	3·9	5·88
Ash (,,)	1·2	1·12	1·48	2·9	4·96
Fat (,,)	3·02	1·74	25·14	23·9	16·74
Protein (,,)	24·94	31·24	23·89	17·15	36·75
Carbohydrates (per cent.)	60·04	55·80	45·59*	52·15†	35·67
Calorie value (per lb.)	1708	1690	2339	2188	2053

* Containing 0·66 per cent. crude fibre.
† ,, 5·90 ,, ,, ,, ,,

Flour.—As ordinary flour contains 11–12 per cent. of protein and 75 per cent. of carbohydrate it will be evident from the figures above that a considerable amount of gluten has been added. This is, of course, reflected in the low percentage of carbohydrate.

Macaroni.—It is stated that this preparation contains over 30 per cent. of protein, a claim which is upheld by the figure quoted. The carbohydrate (starch) content of ordinary macaroni is about 75 per cent., whereas the amount in the Energen brand is some 19 per cent. lower. This increase of protein accounts for the rather dark colour.

Digestive Biscuits.—It will be noticed that in these biscuits the fat and protein contents are very high, and the carbohydrate correspondingly low. The balance between the three principal constituents is well arranged, and the flavour is not unduly rich.

Endobran Biscuits.—These contain a considerable amount of bran-like material which although not of high nutritive value plays a part as a peristaltic agent.

Cocoa.—Since ordinary good grade cocoa powder contains 24 per cent. of fat and 19 per cent. of protein, it will be apparent that the Energen preparation is enriched with a considerable amount of gluten, the fat content being proportionately low.

All of these foods are well prepared and attractively packed. The figures quoted by the Energen Company for the calorie value of their preparations are slightly lower than those we find.

THE LANCET.

LONDON: SATURDAY, JULY 4, 1931.

EPSOM COLLEGE.

In February last the Council of Epsom College issued a questionaire to the governors of the College with the intention to ascertain a collective view on a proposal, advocated by the Council, to abolish the existing method of electing pensioners, scholars, and annuitants. At the present time the results of these elections are determined by the votes of the whole body of the governors. This method in the early days of the inception of the College worked well, but with the increase (and increasing) size of the constituency it has been felt by many no longer to meet the situation with fairness. The risk was seen to be becoming large that the best candidates would not always meet with success, and among the reasons for this opinion one was paramount, when the selection of the foundation scholars was at issue. The friendless child was at a serious disadvantage, while he might be exactly the child whose benefit was intended by the originators of the Foundation. Further prompt help could not be forthcoming while the expensive procedure of collecting votes was going on.

The questionaire met with a response overwhelmingly in favour of a drastic change of procedure suggested by the Council. Votes were recorded by 3862 governors, being over 90 per cent. of the constituency, in favour of the reforming proposal, while only 318 governors voted against it. Having therefore a verdict of nearly 93 per cent. in favour of the change, the Council decided that, after the annual general meeting of the following June, an extraordinary general meeting should be held to obtain authority for the Council to give effect to the wishes of this large majority. The decision of this meeting is recorded elsewhere, and must have given great pleasure to Dr. Raymond Crawfurd, and the existing Council, who have promoted this vital change for the better in the constitution of the College. The resolution authorising the Council to effect the abolition of the present method of election of pensioners, foundation scholars, and annuitants, by the governors and to substitute a procedure of election by a committee appointed by the Council was passed unanimously, a result which was particularly gratifying because the complete concord of view among the governors made it easier for the legislation, necessitated by the change of constitution, to be obtained without expense to the College. The procedure has been made possible by the sympathetic attitude of the Board of Education and the Charity Commissioners.

The new electing body will contain 10 members of the sitting Council, and 10 governors of the College, not being members of the Council. The exact way in which this personnel should be chosen has not been actually decided, and it is a matter which requires some thought. On the principle of general suffrage every supporter of the Foundation had a potential voice in the choice of the beneficiaries, but the outcome of the elections might not reflect the objects which should be in view. The change in the machinery of election by which a small committee is given the responsibility of the whole constituency must lead to a far surer recognition of individual claims, but it will be necessary that the constituency should feel that their responsibility is being exercised by a representative body. The projected scheme, as outlined by Dr. Crawfurd, should meet the case. Under this scheme the 10 members of the selection committee, selected by the governors from without their own body, will represent different interests in different localities upon a rota system, ensuring that the whole constituency will have, as time passes, the particular opportunity of exercising voice.

◆

FURTHER REPORTS ON MUSCLE EXTRACTS.

The claims made for the value of extracts of muscle and other tissues in circulatory disorders [1] are being put to further test. U. S. v. Euler and J. A. Gaddum, working at the Medical Research Institute, have studied the depressor and vasodilating action of certain tissue extracts, and the possible nature of such depressor substances. They conclude [2] that at least five different types of such vaso-dilator substances may occur in tissue extracts. These are: (1) histamine, (2) choline and choline esters, (3) substances allied to adenosine, (4) and (5) two hitherto unidentified substances not belonging to any of the first three groups. One such substance which has been called kallikrein is present in urine and pancreas; the other v. Euler and Gaddum have prepared by acid-alcohol extraction from a number of organs such as small intestine, brain, stomach, and bladder. Experimentally it is found that adenosine and its allies slow the heart, whilst kallikrein accelerates it; all these substances appear to lower appreciably the arterial blood pressure in laboratory animals.

Clinical trials of such tissue extracts—"circulation hormones" has been suggested as a name for them—have been extensively carried out on the Continent. A recent questionaire sent by Dr. R. von den Velden to a number of physicians in Germany, Austria, and elsewhere shows [3] a great diversity of opinion as to their therapeutic success. This may be partly owing to the large number of different preparations that have been employed—the most popular being lacarnol prepared from skeletal muscle—and to the different route by which they have been given. The conditions for which these preparations have been principally used have been angina pectoris, high blood pressure, arterio-sclerosis, and peripheral vascular disorders such as Raynaud's disease. It seems legitimate to draw certain tentative conclusions from the results. First, that the action of the various preparations—myotrat, eutonon, myoston, kallikrein, lacarnol, angioxyl, and others—is essentially similar. Secondly, that little or no favourable effect is to be expected from tissue extracts in cases of myocardial weakness or of cardiac irregularity. In spite of a few contrary experiences the great bulk of opinion is that tissue extracts play no part in the treatment of these conditions, and that where digitalis is indicated it should under no circumstances be replaced by these preparations. As regards high blood pressure opinions are very diverse. The majority of clinicians whose opinions are given find little improvement in the subjective complaints. Some record definite lowering of pressure with considerable clinical improvement; others using the same preparation have seen little or no effect. Clearly cases may differ so widely in character and severity as to make comparison difficult. In intermittent claudication there are very favourable reports, as also in some cases of endarteritis obliterans and gangrene of the extremities. In some patients, however, the latter conditions have been made worse by the injections and caution is undoubtedly required in their use in these cases. In coronary disease, and particularly angina pectoris, many speak enthusiastically of these preparations and a favourable influence on them is reported by the majority of writers. Lessening in the severity and frequency of the attacks is the rule, though again a few have noted partial or complete failure. It would seem, however, that occasionally reactions of an unpleasant nature may occur, though more complete purification and removal of protein from the extracts have lessened their frequency.

[1] See The Lancet, March 7th, p. 533.

[2] Jour. Phys., 1931, lxxii., 74.

[3] Deut. Med. Woch., 1931, lvii., 672.

To sum up, it may be said that these new "circulation hormones" are not entirely without risk, and it is still necessary to urge caution in their dosage and administration. On the other hand, there can be little doubt that in these new organic extracts we have an active therapeutic agent whose precise use and limitation is still to be determined.

PHYSICS: OLD AND NEW.

THE exact sciences have a fascination for the medical man, who humbly accepts the fact, of which he is often reminded, that the biological discipline which he follows is based on less sure foundations. Physics especially attracts his envious attention, since occasionally he is allowed to build, according to his poor capacity, some useful superstructures on the outlying portions of what he believes to be firmly established groundworks. In the past these superstructures were usually carried to a point and then broke down through failure of knowledge on the biological side—as in optics, where the physiological aspects of the mechanism of vision remain obscure. But more recently, in some directions where medical progress depends on a clear conception of physical phenomena this picture has not been forthcoming. For example, clearer differentiation of the physical properties of all kinds of rays emitted in the course of radiotherapeutic measures must precede the acquisition of any exact knowledge of their action on each of human tissues; and the otologists have had to wait long (see the discussion on p. 18) before a standard tuning-fork has been devised.

If one approached in this rather querulous spirit the exhibits displayed on June 23rd by the National Physical Laboratory at Teddington, he could find many targets for quips, but he would be exposing rather his own ignorance of the progress of physics during this century than indicating the claims of the biological sciences to have caught it up. All departments of the laboratory afford examples of the way in which the very methods of applying to practical uses knowledge already gained have suggested other directions in which research must be pursued. This twofold activity characterises nearly all departments of the laboratory and is especially noteworthy, perhaps, in the departments of Aerodynamics and in the William Froude Laboratory. Here the rapid growth of test work connected with ships has necessitated the construction this year of a new tank which, when completed, will measure 678 by 20 feet, being thirty feet longer and ten feet narrower than the Yarrow tank now in use. It is noted that a 30 per cent. reduction in fuel consumption has on occasions resulted from submitting a model of a proposed ship to tests in this laboratory. It is possible, moreover, to determine the force exerted by wind on the deck erections of ships by towing models upside down through water, the erections being attached to a flat-bottomed raft. In this way new arrangements have been designed which reduce the power expended in driving ships against strong winds. Another branch of research in this department is likely to be even more important to shipping. Recent accidents to large vessels on or near a coast have emphasised the need for still further improvements in aids to navigation. One of the most promising methods employed at present is known as the rotating beacon. In this system a continuous transmission is maintained by a shore station, the transmitting aerial rotating uniformly at a speed of one revolution per minute. The transmission from the vertical coil has a narrow beam of silence which rotates with the coil. If the transmission is received on a distant ship, the navigator in the ship can ascertain the bearing or direction of the beacon by measuring the time which elapses between one of the signals and the moment when the beam of silence falls on the ship. An apparatus here exhibited shows how the signal can be received and recorded on a drum which rotates in unison with the beacon, the direction of the beacon from the ship being thus measured automatically. In the Physics department considerable progress is being made in devising convenient ways of measuring sound. On the one hand measurements and analyses are made of the actual energy in the sound waves, and on the other a simple estimate is made of the overall loudness of the noise as heard by the ear. On a convenient scale of loudness with zero at the threshold of hearing, sounds become painful at about 130 "degrees" above threshold, where each degree, known as a decibel, is approximately the least change in loudness perceptible to the ear. The level of conversational speech is at about 50–60 decibels above threshold. Aeroplane cabin noises are at present in the region of 80–110 decibels above the threshold. Eighty decibels correspond to the level of the noise in a tube train. It is almost impossible to converse in a loudness level of 110 decibels, even by shouting. In street traffic and in ordinary trains the noise ranges from 50–70 decibels above threshold, and efforts are being made to reduce noise in aircraft cabins to such a level.

Far indeed is the horizon of physics envisaged by the National Physical Laboratory from the conception imposed by dogmatic chapters on heat, light, sound, electricity, and magnetism in the elementary text-books of the pre-medical course. We all knew well enough when following this course that the ground would grow more difficult if we pursued the path, but most of us gratefully shut the gate at the place where it let us into the more congenial fields of physiology and anatomy, and never reopened it. This was a mistake which future generations will hardly be permitted to make, since biophysics, younger even than biochemistry, promises to be no less important. At least the newer developments of physics have shown the futility of any attempt to distinguish between the more, or less, exact sciences. All our standards are suffering change, even, may be, the most fundamental. Almost the first thing we learnt in elementary physics was the importance of an arbitrary unit of measurement. The standard yard was defined as the distance at 62° F. between two lines on gold studs inserted in a metal rod under the custody of the Board of Trade. Lest this Imperial Standard should be lost through any cause, as was its predecessor by fire, four replicas were embedded in the masonry of, or kept securely in, various national institutions. Now even this standard is found wanting. At the National Physical Laboratory experiments are proceeding with a view to establishing a wave of light as the universal length unit in substitution for the present material standards represented by the Imperial Standard Yard and Prototype Metre. Apart from the advantages of indestructibility and permanence, the proposed unit is said to offer possibilities of increased accuracy in reproduction and measurement. The work so far accomplished indicates that the yard and metre lengths can be reproduced to an accuracy of about four millionths of an inch, and further refinements of the apparatus are likely to increase the accuracy to one millionth of an inch. Our rejoicing at this possibility is tempered by a regretful glance at the school text-book which first familiarised us with this Imperial Yard, which from something that had seemed to be a natural phenomenon in the home even of a dressmaker or a carpenter became suddenly elaborated into a lesson. Those who are loyal to material standards may take comfort from the fact that nearly 40 years ago A. A. Michelson showed that a standard of length might be restored, if necessary, by reference to the measurement of wave-lengths of light, but that the desired degree of accuracy, to a millionth of an inch, has not even yet been, and may never be, achieved.

◆

THE ORDER OF ST. JOHN.

No surviving institution connects the British Empire of to-day so closely with what we regard as the ages of chivalry as the historic Order of St. John of Jerusalem, the English branch of which last week celebrated with fitting ceremonial the centenary of its revival. The "Grand Priory in the British Realm of the Venerable Order of the Hospital of St. John of Jerusalem" traces its ancestry back to the little hostel for Christian pilgrims created by Brother Gerard which Godfrey de Bouillon found in Jerusalem when he captured the Holy City in 1099. From this small beginning was developed a great Order of Chivalry pledged to defend the Christian faith and to serve the sick and poor which eventually became a military power with all the attributes of Sovereignty until it was so smashed to pieces by Napoleon that on the Continent it survives only as a highly exclusive body of Roman Catholic nobles of sixteen quarterings. For four centuries the Order occupied a splendid place in England with its great central Priory in Clerkenwell, the scanty remains of which now once more house it. At the Dissolution it suffered the fate of all other religious houses and it was not until 1831 that it was resuscitated, and not until 1888 that it was established by Charter as the Order of St. John of Jerusalem in England with Queen Victoria as hereditary Sovereign Head and Patron. How much the Order owes to the Royal Family is suggested by the presence at the centenary service in Westminster Abbey last week of nearly a dozen members of the House of Windsor, with the Duke of Connaught, the Grand Prior, at their head. At that service the Archbishop of Canterbury preached a sermon which was accorded the distinction of being broadcast throughout the world. The Order is associated in the minds of most people chiefly with the work of the St. John Ambulance Association which, starting as a teaching body in 1878, developed a decade later into the St. John Ambulance Brigade. The activities of the Brigade in the war, associated with those of the Red Cross, can never be forgotten, and in peace its 70,000 members of both sexes are almost daily doing invaluable work in street and home here and in the Dominions. Almost half a century ago the Order renewed its immediate connexion with Jerusalem by opening the Ophthalmic Hospital on "an impressive site overlooking the Temple" (to use the Primate's words), and here works of mercy are freely extended to men and women of all races and beliefs.

Manchester Babies' Hospital: Annual Report. In 1930 this hospital, which was founded 17 years ago by women doctors and was originally staffed entirely by women, and admits patients ranging in age from a few hours to two years and a half, had 604 in-patients and 088 out-patients, an increase from 406 in the preceding year, and a growth in attendances from 1325 to 2013. Of the in-patients, whose average stay was 53 days, 90 died, the most frequent causes of death being prematurity (29) and broncho-pneumonia (18). The after-care work ensures that the majority of ex-patients are kept in view.

ANNOTATIONS

OFF-DUTY WORK.

AN interesting recommendation was made last week by the central public health committee of the London County Council for the council's acceptance. It has long been the practice in the mental hospitals under the council's control to allow the medical superintendent to hold an appointment unconnected with his office, on such conditions as the council may decide proper. He may, for instance, be physician to an out-patient clinic at a general hospital, and in fact has often been such. Application has now been made for this permission to be extended to medical officers of other types of hospital which have more recently come under the council's control. The deputy medical superintendent of Fulham Hospital has the opportunity of becoming assistant radiologist at the National Hospital, Queen-square; the assistant medical officer at St. Mary (Islington) Hospital would like to apply for the appointment of honorary medical registrar at the Maida Vale Hospital for Nervous Diseases. On his behalf it was stated that the appointment, which would involve attendance on two or three afternoons a week, would be carried out during normal off-duty hours. The committee's recommendation was made in no grudging way. "We are of opinion," they say, "that the staff generally should be encouraged to hold such appointments, as association with outside medical work provides valuable experience which will be of benefit in carrying out their duties under the council"; and the grant of similar facilities is to be customary provided that (1) the appointment is an honorary one, (2) the holding of it shall not interfere with the efficient discharge of the officer's ordinary duties, and (3) the work is done in off-duty hours. The position is interesting, for the question of the employment of off-duty hours in a full-time appointment has provided many conundrums, some of them so difficult of solution as to require the aid of medical defence societies. Broadly speaking, the employer of a medical person cannot prescribe or prohibit any form of unpaid off-duty employment which does not contravene his or her terms of service, and, unless it is expressly stipulated in these terms that no other moneys whatever shall be received by the officer in virtue of his medical qualification, it is difficult to see how the prohibition of payment can be enforced. Where the whole-time salary is on a generous basis, the question of supplementing it will hardly arise, but this is not always the case. The arrangement suggested in London, if it should become general, will result in a liaison between the voluntary and municipal hospitals which must have its effect on the future of both. A possible risk of widespread response to this permission might be to endanger the practice of offering modest honorariums for hospital posts, such as registrarships, to enable young men or women to keep themselves by doing useful routine work while waiting for a vacancy on the staff.

DIATHERMY AS PYREXIAL AGENT IN G.P.I.

SINCE first Wagner-Jauregg brought hope to the black prognosis of general paralysis of the insane, experimentation has been mainly concerned with various ways of producing fever. The essential element in the cures that have been attained has seemed to be the pyrexia induced by the remedial agent, and on the whole the opinion of psychiatrists still agrees with that of the pioneer workers in regarding the plasmodium of malaria as the best agent. But to give a man malaria is a serious responsibility, and could only be justified by the appalling future before these patients in the absence of treatment and the very considerable measure of control of the pyrexia afforded by quinine. It seems strange that the relatively much less harmful type of pyrexia that can be induced by diathermy has not been more widely tried. Drs. C. A. Neymann and M. T. Koenig[1] have found that it is not only far safer than infective methods but also more successful, especially with depressed patients who are apt to prove more resistant to treatment than the expansive ones. Neymann and Koenig have treated 50 cases selected at random, over half having a duration of from one to five years, and have compared the results of malarial, rat-bite fever, and diathermy treatment. About 20 per cent of the patients had previously been treated with malaria and tryparsamide without appreciable results. The method of administering diathermy was that described by C. A. Neymann and S. L. Osborne,[2] but no patient was given more than 12 treatments. This, the authors say, is not enough, but the work was experimental and they were limited by circumstances. Most patients had between one and two hours' pyrexia of over 103·5° F. after each treatment. The death-rate was 18 per cent. for malaria, 10 per cent. for rat-bite fever, and nil for diathermy. The results with malaria were as good as is usual nowadays; the remissions in rat-bite fever were brief and occurred only in 8 per cent. Diathermy gave 24 per cent. remissions as compared with 22 per cent. after malaria. The criterion of remission is that the patient should regain insight and be able to leave the institution and earn money. Most of the cases only began to show improvement after the eighth or tenth treatment. The improvement rate—short of full remission—was 26 per cent. for diathermy and 22 per cent. for malaria and rat-bite fever. Of seven depressed patients treated with one or other of the fevers, only one showed improvement, while of four depressed patients treated with diathermy two went into remission and the other two were sufficiently improved to be put on parole. The serological changes did not correspond with the clinical changes; some demented cases improved serologically but not clinically, and vice versa. There are no complications in or contra-indications to diathermy treatment, provided the proper electrodes are used and the proper technique is applied, and as many as 50 treatments can be given without ill-effects. The dosage can be measured with scientific exactness, and the method can be applied by any practitioner acquainted with the elements of electrotherapy. The advantages of this method are so obvious and the disadvantages of other forms of induced pyrexia are so well known that if the results obtained by these American workers are substantiated a very great advance has been made in clinical psychiatry.

RESEARCH FACILITIES AT LINCOLN'S-INN FIELDS.

THE provision in 1930 of laboratories for research workers in rooms adjoining the Museum at the Royal College of Surgeons is described by Sir Arthur Keith in his annual report as an important development of the services which the Museum of the College renders to surgery. Hitherto research work has been carried out by the officers of the Museum and by men who found in the Museum material which elucidated the subject of their inquiry. The laboratories now provided are intended to meet the needs of another class of men altogether—young men who aspire to become members of the surgical staffs of our great hospitals.

---

[1] Jour. Amer. Med. Assoc., 1931, xcvi., 1858.

[2] Ibid., xcvi., 7.

Four new research scholarships, offering £500 a year for varying terms of years, are being founded, of which the Melchett, the Bernhard Baron, and the Beaverbrook are already in working order, being held respectively by Mr. J. H. Thompson, Mr. E. G. Muir, F.R.C.S., and Mr. H. J. Burrows, F.R.C.S. A fourth scholarship is to be provided from the funds of the College. Mr. Thompson is seeking to isolate the growth-inhibiting factor from parathyroid material. Mr. Burrows is engaged on tissue culture, and Mr. Muir is studying the comparative anatomy, physiology, and pathology of the prostate gland. One of the laboratories has been assigned to Dr. G. Scott Williamson, who holds a Mackenzie Mackinnon Fellowship, and to Dr. Innes Pearce, who is working with him on the nature of the substances secreted by the thyroid gland in health and disease. Voluntary workers who are investigating problems relating to the practice of surgery are also accommodated in the laboratories, as far as space permits, and six of these are at present receiving hospitality. For the convenience of workers an animal hut has been erected on the roof of one of the laboratories, the College having gained recognition as a centre where animal experiments may be performed. These facilities, together with the research farm in the country, of which the plans are set out on p. 39, should give a fresh stimulus to surgery.

STANDARDS FOR SPAS.

HYDROTHERAPY has long been recognised as an important branch of medical treatment and a concise but comprehensive survey of the various waters available is long overdue. When the scheme by which spa treatment will be available to members of approved societies comes into operation, it will be essential for every panel practitioner to possess some knowledge of the spas and their treatments. They will have good cause to welcome the first instalment of an International Register of Spas and Mineral Waters, just issued[1] by the International Society of Medical Hydrology. The desirability of uniform methods for the expression of data led to the appointment four years ago of a standard measurements committee, under the chairmanship of Mr. S. Judd Lewis, D.Sc., which will promote the compilation of national registers of waters to form the basis of an international register. When this is done, accurate and comparable information regarding the spas and their waters will be available for every one interested. In the past analysts have expressed their results in various ways, most of them unintelligible to medical men. In the register a common form of expression designated by the letters "I.S.M." (International Society of Medical Hydrology) is given, but provision is made for the inclusion of the same results expressed in the manner customary in the country concerned and designated as "National." In the British register, the figures will at the outset be given in milligrammes per litre (I.S.M.) and grains per gallon (National). It is hoped that the National form of expression will ultimately become redundant. For the benefit of those who are accustomed to think in terms of salines, instructions are given for the calculation of the most probable combinations of the ions present in such waters and their mode of expression, but it must be borne in mind that all such combinations are hypothetical and arbitrary. Physical data are to be recorded in a standard manner, eliminating for example the confusion that arises when radioactivity results are expressed sometimes as millimicro-curies, sometimes as Maché units. Standard forms are given for recording geographical, climatological, geological, and topographical data, and the register provides for the classification of the waters according to their chemical, physical, and medical characteristics. Local information will include *methods of treatment available, facilities for* the investigation of disease, and a list of the diseases and disorders suitable for treatment. There must remain for long enough a great gulf between the precision of the analytical data and of the deductions for treatment based upon these data. Chemical analysis is a science and medicine an art; but without accurate data, treatment will remain purely empirical. Dr. Lewis and his colleagues have provided a sound basis for the superstructure that is to come.

THE AUSTRALIAN MEDICAL SERVICES IN THE WAR.

A HISTORY[1] of Australian medical coöperation in three very different campaigns during the late war gives a good picture of the gallant fight made against unexpected obstacles on all fronts. Many and grave were the problems of the Australian Medical Corps. On Gallipoli, for example, on April 25th, 1915, it was difficult to land, as is seen in the picture on p. 132 of this history. *The narrow beaches and steep rugged* hills were hard to climb even for men without equipment while G.H.Q. was so absorbed in the problem of reinforcing an uncertain attack as to have little time for thought for the wounded. Casualties, who had to be brought down the narrow ways impeded the reinforcements, congested the beaches, and awaited hospital ships while it was still doubtful whether ships would not rather be needed to remove an unsuccessful army. But the Navy, less closely involved, lent Neil-Robertson stretchers for lowering wounded down the cliffs and *the indefatigable senior medical* officer of *London* got many wounded off to the five ships his admiral had detailed. Thus of over 4275 casualties, 3380 were embarked for Egypt on April 26th and 27th. Later, the plague of flies which raised the number of sick all through the summer was followed by the great attack in August, to prepare for which the Australian A.D.M.S had to plead for help in clearing the beaches. Sinai and Palestine provided different problems, in some ways easier. Twice in 1916, at Magdhaba and Rafa, ambulances were recalled because attacks were said *to have failed, but the fighting lines*, who had not been told they were beaten, went on and won their battles, which was satisfactory enough, but it was hard to pick up their wounded promptly. The strenuous antimalarial campaign along the front in the summer of 1918, especially in the valley of the Jordan, 1280 feet below the sea, tired the troops; but had they known that Liman v. Sanders would later[2] charge his failure to the epidemics of malaria and dysentery, how they would have been encouraged! Of the successful cavalry operations in Sept., 1918, every one is aware, but we have not before met so detailed a description of the confusion found by the Australian Force on Oct. 1st in the hospitals of Damascus. They were without food, without drugs or appliances, without staff; all these deficiencies had to be made good in the teeth of two fierce, and by bad luck simultaneous, epidemics of malaria and influenza, which broke out on Oct. 5th. These epidemics immobilised the 4th Cavalry Division in the Lebanon, hardly sparing it enough men to feed the horses; raised the total of Turkish prisoners in the hospital from 900 to 2000; and dealt not too unkindly with a medical unit if it incapacitated a mere half of its personnel. The Australian Light Horse lent 100 non-commissioned officers and troopers, the D.M.S., E.E.F., at Ramleh sent up 100 R.A.M.C. orderlies, and somehow the situation was saved. The Anzac Field Laboratory should be mentioned. Its work was pursued far forward in the danger line, at Aleppo and Aintab, and at Jerablus on the Euphrates; its staff had to deal with cholera, diphtheria, oriental sore, dysentery, and especially malaria, achieving 32,000 examinations in two and a half years, with much travelling as well. It is interesting to read praise of prophylactic quinine; 10 cases of malaria occurred in 10 men thus treated to every 23 in untreated men during May to August, 1918, and subsequently grs. 10 daily were ordered for all troops in the great advance. It is noted that after 10,000 prophylactic treatments at Port Said for venereal disease only six cases of disease were reported; but such good results were far from universal. In New Guinea malaria and dengue were the chief troubles of the Australian force. Here prophylactic quinine was thought to have secured a lessened proportion of blackwater fever. This and other experiences will be discussed in a later volume, which promises to be as interesting as its predecessor.

MEDICO-LEGAL WORK IN PARIS.

A LARGE body of detective fiction has invested the Sureté with a halo of glamour. While possibly no more romantic than any other public service, the Sureté deserves its reputation for efficiency and resource. As Dr. T. H. Blench pointed out in a paper read before the Medico-Legal Society on June 25th, the Sureté is the criminal service of the Prefecture of Police and must not be confused with the Sureté Générale, which comprises the organisation of provincial police and is under the direction of the Minister of the Interior. The *police judiciaire* of the Sureté are guided by the three principles of the division of work, observation, and classification. Work is divided into four brigades. The criminal brigade deals chiefly with murders and important robberies; it is composed of skilled detectives aided by very complete scientific equipment. The brigade concerned with public highways is adept in disguise and languages. The mixed section, which deals with morals and drugs, frequents the theatres and music-halls and is expert in the niceties of evening dress, jewellery, perfumes, motor-cars and American dancing. All these brigades are assisted at need by the Service d'Identité Judiciaire. This department records the finger-prints of criminals and measurements of the body, including those of the skull, the right ear and the left foot, arm, and middle and little fingers. Identification is completed by a note of any scars, nævi, tattoo marks, or other peculiarities. The Service maintains a section the special function of which is the speedy analysis of the circumstances and surroundings of a crime; it includes a photographer, a finger-print expert, and a man whose duty it is to draw a plan of the area. There are also experts in bullets, powder-marks, blood-stains, and forgeries, in the detection of which the ultra-violet ray is of great value. Other uses of the ultra-violet ray are the analysis of substances suspected of being drugs, and the examination of semen stains.

Dr. Blench gave an interesting description of the Medico-Legal Institute of Paris, which is situated some two miles from the Palais de Justice on the Quai de la Rappée, and was completed in 1923. It grew up from the old Morgue, and contains laboratories, post-mortem rooms, facilities for instruction of students, a museum, and a library. It is able to make every kind of investigation on corpses, post-mortem specimens, foodstuffs, and every substance or object that may possess forensic significance. It instructs—besides medical students—post-graduates, magistrates, law students, police officers, and others concerned with the administration of justice. The course comprises coroner's inquests and practical investigation, and candidates are prepared for the diploma of médecin légaliste in the University of Paris. Dr. Blench pointed out that the training made medico-legal instruction in this country appear very meagre. During the ensuing discussion several speakers stressed the advantages that would be derived from the possession of a similar institution in this country. There can be very few medical men who would not profit in their daily experience from a course of instruction and from the constant coöperation of a well-equipped medico-legal institute. It would also facilitate the administration of justice. In our present hand-to-mouth system important investigations are entrusted—sometimes at very short notice—to an expert who has to rely for help far more on his genius and personal contacts than on any kind of permanent organisation. The cost of erection and of maintenance of a medico-legal institute would be considerable, but in the interests of justice the money spent would be well invested.

ANOTHER ANTHELMINTIC.

IT is well established that carbon tetrachloride produces fatty degeneration with necrosis of the liver, and less fully realised that it may also cause marked damage to the kidneys. Lamson and his colleagues[1] stress its third risk, for after study of the records of the International Health Division of the Rockefeller Foundation they have been convinced that it was only after this drug began to be used in hookworm campaigns that there first appeared certain disquieting reports. These related to treated patients who had shown evidence of activation of ascaris. Some only vomited the worms; others died, death being caused by worms blocking the air passages or knotting themselves into a ball which obstructed the gut. The search for a new drug which would avoid these risks led to the investigation of hexylresorcinol. This is a white waxy crystalline substance slightly soluble in water or mineral oil and readily so in alcohol, glycerin, and vegetable oils. Dissolved in olive oil under the name Caprokol, it has been widely used, at least in the United States, as a urinary antiseptic in doses up to 1 g. three times a day, continued for weeks without ill-effect. Lamson and his co-workers find that in dogs hexylresorcinol in doses of 0·6 g. may produce no lesions in the stomach, or there may be congestion of its mucous membrane, varying from reddening of small areas to implication of the whole with petechial hæmorrhages. Lesions disappear within 48 hours. But side by side with this congestion must perhaps be put the vomiting which has been induced by giving to children less than 8 years old a dose of 1 g.; it is probably significant that this symptom has been almost limited to those who have eaten shortly after taking the drug. As judged by colorimetric tests, a fraction only of the drug is excreted in the urine, and, indeed, the major part remains in the bowel. The drug is unpleasant to take; the taste is easily disguised in glycerin or vegetable oils, but if this be done anthelmintic efficiency is greatly lessened. Accordingly in the work reported the drug was given in hard gelatine capsules; but these must be freshly filled, since the drug acts on the capsule and renders it unstable. The single doses given varied from 1 g. to 0·4 g.; many of the patients treated were children, and the information is not so arranged that it can be determined whether or not the smaller doses were given to these. It is stated that for adults a dose of 0·5 g. was less effective than a larger one.

---

[1] Lamson, P. D., Brown, H. W., Robbins, B. H., and Ward, C. B.: Field Treatment of Ascariasis, Ancylostomiasis and Trichuriasis with Hexylresorcinol, Amer. Jour. Hyg., 1931, xiii., 803.

The outstanding feature in regard to anthelmintic value lies in the readiness with which the drug combines with albumin and becomes inert. In the intestinal canal this is held to limit its action to the superficial layer of the epithelium, in spite of the vascular dilatation and rupture of blood-vessels which the writers themselves have reported beneath this. At all events the eating of food even five hours before taking the drug lessens its vermicidal power so strikingly that the writers believe, though they do not seem to have tested the matter, that to get the best effects from it nothing should be taken on the previous evening except a little bread and milk. Salts should be taken on rising, hexylresorcinol several hours later; and the first food of the day four or five hours after treatment.

The results of treatment have apparently been assessed on the examination of a two-hundredth of a gramme of fæces, and these workers italicise the point that their results are based on the accuracy of the diagnostic method they used. In ascaris infection treatment has given results in different groups varying between complete disinfestation on the one hand, and on the other a complete failure to disinfest but with a lessened number of worms, the critical factor in this case being the taking of food or the use of an unsuitable vehicle. In hookworm infection the result in fasting persons of doses up to 1 g. was an observed reduction in eggs by about 80 per cent., the obviously uncured varying from about 40 per cent. to about 60 per cent.; while for trichuris infection the observed reduction in eggs in the fasting was about 50 per cent. and the obviously uncured lay between about 50 per cent. and 80 per cent. Owing to the large numbers of eggs passed by a female ascaris it cannot reasonably be doubted that those persons who appeared to be disinfested were actually rid of all female worms. In the case of hookworms and whipworms the real percentage of uncured was undoubtedly considerably higher than the figures suggest, for, if a worm lays eggs at such a rate that one egg is found in a thirtieth or a fourtieth of a gramme, disinfestation cannot be determined by the examination of a two-hundredth of a gramme. The writers add valuable tables which show the estimated anthelmintic efficiency obtained in these infections by other workers with other drugs. It does not seem that hexylresorcinol will displace them by reason of greater potency, particularly in view of the strict and intelligent coöperation which the patient must give before even reasonably good results are obtainable with the anthelmintic.

THE RELIEF OF PAIN IN CANCER OF THE BLADDER.

THE discussion on the treatment of inoperable carcinoma of the bladder, reported on p. 20, brought to light much that is interesting. Everyone who has had to deal with this type of case must have been impressed by the amount of suffering that vesical carcinoma often entails to the patient, and by the inefficacy of present methods of treatment to relieve it. In spite of the advances made in radium therapy it was admitted both by Mr. R. Ogier Ward, who opened the discussion, and by the subsequent speakers that results obtained in inoperable growths of the bladder are disappointing. Although in Mr. Ward's hands the implantation of seeds through a cystoscope has brought relief to a few patients, no case of cure has been reported, and many of the speakers admitted that the more usual practice of transfixing the growth with radium needles has actually increased, rather than reduced, the sufferings of their patients. This failure of radium can in part be accounted for by the special difficulties that exist in eradiating the bladder, but it is probable that this is not the sole explanation. The tendency in radium treatment to-day is to diminish the dose of the element and increase the time over which it is allowed to act. In the treatment of carcinoma of the cervix it has become customary to repeat the treatment after a short interval, and it is possible that were this fractional method to be adopted in vesical carcinoma better results would be obtained. The use of massive doses in an attempt to destroy a growth at a single sitting only results in the production of a sloughing sore and an increase of the patient's discomfort. But whether by improved technique we can ever hope to produce in bladder growths the same satisfactory results as those obtained in cervical or mammary carcinoma is doubtful, and it is important, in the meantime, to explore every possible way of relieving the patient of the worst of his sufferings. For this reason the latter portion of Mr. Ogier Ward's paper, in which he deals with the use of nerve section as a means of abolishing the agonising pain usually associated with inoperable bladder growths, is of special interest. So far, two methods of doing this have been used, namely, chordotomy, or division of the antero-lateral tracts, and removal of the presacral nerves. Of these methods the former is, of course, the more reliable, since it effectually blocks all painful stimuli coming from the pelvic viscera and lower limbs, but as it entails a somewhat severe operation its use must be limited. Destruction of the presacral nerves has the advantage of being a less serious operation and one that can be performed through the same incision as that required for an exploration of the bladder. Although it is difficult on anatomical grounds to explain the rationale of destruction of the presacral nerves it would appear, both from the work that has been done in Germany, and from Mr. Ogier Ward's more limited experience, that the method gives good results, even when the pain is not limited to dysuria. Possibly, as Mr. Ward suggests, the action is an indirect one, due to the alteration in the tone of the bladder wall which the interference with its nerve supply produces. At any rate the method is one that should be fully tested.

PSYCHOLOGY OF THE EMIGRANT.

EMIGRANTS of all classes desiring to live permanently in Canada must submit to a medical examination prior to embarkation and certain British practitioners have accepted the responsibility of conducting these examinations under a roster scheme. The *Medical Officer* in its current issue quotes a note which is being included in the instructions to these practitioners which is of interest chiefly for the emphasis laid on the psychological rather than on the physical stress associated with a complete change of environment. Not only climatic changes but comparative isolation in outlying districts, change in money standard, food, cooking, and dwellings; complete change in local interests and details regarding social life and activities; difference in customs and routine methods of doing work and business generally, all these tend to produce a period of home-sickness of such severity as to be really disabling. Disappointment may arise, too, from the erroneous idea that less work will produce a better living in the new country. Moreover, the release from the restraining influences of the home environment is often too much for persons lacking in self-control or moral responsibility.

It is held to be of particular importance, therefore, in examining prospective emigrants to detect not only the obvious physical or mental defective, but also those individuals who possess defective judgment, instability of the nervous system, or who are emotionally hypersensitive. This task will be made more difficult by the fact that it is often just these people who have been oppressed by the difficulties of life in Europe and are often anxious to make a new start. They may be unlikely to make good elsewhere, but it seems to us harsh to deprive them of the opportunity. The Canadian government believe, however, that a close and friendly coöperation between the British medical man making the examination and the Canadian medical officer, specially trained in immigration medical work, will mitigate suffering and hardship on the part of the immigrant, as well as relieve the financial burden on Canadian public funds resulting from the physical or mental collapse of new settlers.

TUBERCULOSIS CONFERENCE AT MARGATE.

THE 17th annual conference of the National Association for Prevention of Tuberculosis, held last week at Margate, centred on the child, and that for two reasons. It is realised that the secret of the adolescent peak of tuberculosis mortality is probably hidden in the period immediately preceding adolescence. The raising of the school age will enable much more to be accomplished in protecting the child. The various sessions of the conference were devoted to different periods in child life and the appropriate measures of protection. Some of the papers are briefly summarised on p. 22 of this issue. Sir Robert Philip, whose introductory address while directed to the layman's understanding was yet informative to the medical man, expressed a wish that the tuberculin test should become universal. It was our biggest weapon for discovering that infection had taken place, and the basis of our means for protecting the child. Like other speakers, he thought the case for B C G unproved. Closer liaison was desirable between tuberculosis and child welfare departments, and success was to the community which would search out positive reactors and attend to their environment. Dr. Eugene Opie set out attractively his conception of adult phthisis as a second infection, modified by a partial immunity. By means of stereoscopic X ray films and the tuberculin test, grave pulmonary lesions could be discovered in children long before the disease had produced destructive changes. Two per cent. of school-children between 14 and 18 years of age had, he said, dangerous lesions of the lung parenchyma, although only a quarter of them revealed it by symptoms or physical signs. But the view that adult disease develops from latent disease in childhood did not go unchallenged. Dr. N. D. Bardswell said he had found the development of tubercle in adolescence as a rule independent of any previous history of ill-health; and Dr. Letitia Fairfield regarded the entrance into industry as the determining factor. There was no hint, she said, of increased incidence among secondary school-children; why the resistance fell so precipitately on leaving school was an urgent matter for inquiry. The protection of the child during the pre-school and school years was ably developed by speakers. Dr. Midgley Turner spoke persuasively of the "dilution" of tuberculosis by general education of the public; the open case of phthisis was the crux of the problem. He outlined the Sheffield scheme for isolating the infant of a tuberculous mother for twelve months after birth; others doubted whether parents in this country could be persuaded to adopt the Grancher system. Dr. R. H. Crowley described the newer developments of hygiene in schools, and the changing orientation of our education, which is coming to regard the child as a whole. If the conference has immediate results it will be in the direction of making X ray examinations and tuberculin testing more common among school-children throughout the country, and in measures to prevent infection through the open pulmonary case. On the question of infection through milk, opinions were sharply conflicting.

DR. J. A. Campbell Kynoch, Emeritus Professor of Obstetrics at St. Andrews University, died suddenly on June 23rd. He was a graduate in medicine of Edinburgh University, and studied midwifery and gynæcology in Berlin, Vienna, Bonn, and Munich. He was the first Professor of Midwifery appointed when the Conjoint Medical School was established in Dundee and for many years was Dean of the Faculty of Medicine at St. Andrews University.

THE death occurred of Mr. Edward Beadon Turner on Tuesday last, June 30th, at his London residence. For five years a member of the General Medical Council, a medical reformer, health-worker, and athlete, he was well known by a great public outside his profession, and his death will be widely regretted. A notice of his career will be published later.

EXTENSION OF DUDLEY GUEST HOSPITAL.—A new wing of the Guest Hospital, Dudley, was opened by Princess Mary last December, and it has now been decided to erect another similar wing containing two main wards and six single-bed wards, providing 54 beds in all. The work will cost £30,000, and to make room for the additional nurses who will be needed the Helen Thompson Memorial Nurses' Home is to be enlarged at the cost of a private donor. Six months' experience of the new wing has shown that the hospital is still inadequate to the demands made upon it, the waiting list having continued to grow.

PANEL AND CONTRACT PRACTICE

THE INFLUENCE OF HEALTH INSURANCE UPON HOSPITAL PRACTICE.*

BY T. B. LAYTON, D.S.O., M.S. LOND., F.R.C.S. ENG.,
EX-CHAIRMAN, THE LONDON INSURANCE COMMITTEE; SURGEON TO THE THROAT AND EAR DEPARTMENT OF GUY'S HOSPITAL, LONDON.

THOSE who minister to the health of the people are no longer limited to the profession of medicine. There are those who carry out the treatment we order: the nurse, the masseur, and the electrotherapist. There are those who supply us with the wherewithal to do this: the pharmacist and the instrument-maker. There are those who provide for us the accommodation in which it can be done—the architect, the engineer, and the builder. In each of these branches the work has become specialised. And there is the administrator. If I speak more of him it is not that I give him pride of place, or think him either more or less important than the others, but because his importance has not, as yet, been recognised, especially by the medical profession; and when he is recognised it has often been rather to jeer at his failings than to sympathise with his difficulties and to help him in his work. We live, however, in an age of team-work, and whether one deals with the League of Nations or with the organisation of health insurance the work of each has to be fitted into that of another like the pieces of a mosaic.

Administrators may be divided into: (1) those who deal with the health of the people on wide general principles, in the office of the government of the municipality or at the headquarters of the great charitable organisation; (2) those who work out these general principles in broad detail, in the offices of the hospital, of the treatment clinic, or of the ambulance service; and (3) those who carry out the minute details in close association with the individual patient—the social service worker, the almoner, and the secretary. In the background, over all and yet the servant of all, is he who deals with finance.

Of all this elaborate organisation each unit of the people asks two things: to be kept well when in health, and to be returned to it again when health fails. And if this last be impossible they ask to be relieved of pain and discomfort and to be enabled to carry on with their life's work so far as they can.

The art of keeping the people well is of two parts: the first is public health, the second is personal hygiene. With the first, health insurance does not deal; but in our country personal hygiene has always been reckoned as a part of health insurance. This is inherent in the very first words[1] which Mr. Lloyd George used when, as Chancellor of the Exchequer, on May 4th, 1911, he asked leave of the House of Commons to introduce a Bill to provide for insurance, amongst other things, for the prevention and cure of sickness. It is true that as yet but little has been done under this head; but it remains a part of our national policy and may at any time be taken up.

Treatment when Ill.

The doctor holds the key position to this subject. Up to now the medical benefit in the British Insurance Acts only includes services involving the application of skill and experience of a degree or kind which general practitioners as a class can reasonably be expected to possess. Not that it has ever been the national policy so to limit it. The services to be rendered by the general practitioner were the foundation upon which a complete superstructure could later be built. The National Health Medical Service came into force in Great Britain on July 15th, 1912, but the superstructure has not as yet been added. In the spring of 1914 Mr. Lloyd George proposed an extension of the Insurance Scheme to include specialist and laboratory service, and the money for this was actually voted by Parliament on August 4th, 1914. Then came the great hiatus in the even tenor of our ways, and we have not yet reached a new normal of our national life. The result of this is that our National Health Insurance scheme has never had a normal year in which to work. There were but two years in which to get things going before the world went sick. During later years we have worked at it in a period of the world's convalescence.

So far as the past is concerned, I can find no evidence that in England, or at any rate in London, the institution of the National Health Insurance system has had any material effect upon hospital practice. In their out-patient work the hospitals deal chiefly with patients who need specialist treatment. This was not included in our national health scheme, and it is not surprising that the institution of the scheme has had no influence upon the attendances and work of these departments. The out-patient departments dealing with general medicine and surgery do, however, deal with a certain number of cases which should be included under the work that can be done by the general practitioner. These patients were included among those who could not afford to pay the doctor for individual attendances It is probable that there was some decrease in their number when the national health scheme came into being. The decrease, however, was not great. The scheme applied only to the workers, not to those dependent upon the worker, who made up the majority of such persons attending hospital. Actually the worker could not himself afford to go to hospital; the amount it cost him by the loss of pay for half a day's work was greater than the amount he had to pay to see his doctor in the evening. Even though there was some falling-off in the attendances in these departments, in relation to the whole work of a great institution, such as that which I have the honour to serve, the effect was infinitesimal and has not been felt in the general life of the place. It is, however, probable that to-day the system is having an indirect influence which may be felt but of which no statistics can be gained. I put before you, therefore, various suggestions that are adduced from different quarters.

First it is suggested that the practitioner in charge of the case is inclined at once to send the patient on to the hospital as soon as he realises that he is suffering from some condition that would come under the category of specialist services. It is true that the total number of patients attending such departments —e.g., that dealing with diseases of the nose, throat, and ear—has been on the increase in recent years, but there is no evidence to show that this increase is especially among the insured population and is not explained by the general increase in attention to such diseases among the population as a whole.

---

* Abridged from address delivered on June 8th at the Second International Hospital Congress held at Vienna.

[1] Hansard, fifth series, vol. xxv., 609.

If such an increase of attendances among the insured population has occurred, it must be credited to the National Health Insurance scheme that these patients are now getting the specialist treatment that they need.

Again we hear it said that when a general practitioner sends his patient to the hospital he loses touch with him and hears no more about him. This resolves itself into the need of some organisation whereby the clerical work of keeping touch between one doctor and another can be put upon a sound basis and it shall not be left to the energies of a tired specialist to write or dictate a number of letters at the end of a long day.

The provision of additional benefits has resulted in a certain sum of money being paid by the approved societies to the voluntary hospitals. This money has been of value to them, but has not had any direct influence upon the practice in these institutions.

Perhaps the most important way in which the Insurance Acts have had an influence upon the practice of our hospitals is that they have influenced the practitioner in sending his patients suffering from some acute disease into these institutions at an earlier stage of the illness. The evidence in favour of this is quite indirect and it may be due to the slow influence of medical education rather than to the Insurance Acts. That cases are less often sent up in advanced stages of acute disease is, however, all to the good.

The Hospital of the Future.

We turn then to the future. Upon this we can have no evidence. We can but indicate the lines upon which we feel things must evolve. Our great philosopher-statesman of the last generation, John Morley, spoke[2] of the three independent provinces of compromise as being "a wise suspense in forming opinions, a wise reserve in expressing them, and a wise tardiness in trying to realise them." He urged that if a subject is not ripe for practical treatment you and I are not, therefore, entirely relieved from the duty of having clear ideas about it.

> "As it is," he added, "everybody knows that questions are inadequately discussed or often not discussed at all, on the ground that the time is not yet come for their solution. Then when some unforeseen perturbation, or the natural course of things, forces on the time for their solution, they are settled in a slovenly, imperfect, and often downright vicious manner, from the fact that opinion has not been prepared for solving them in an efficient and perfect manner."

We may then agree that it is the building of the superstructure of which the general practitioner service was to be the foundation that will have an influence upon our hospital practice.

This superstructure may be expected to consist of three parts: the provision of laboratory services, the provision of consultation and advice by the specialist branches of the medical profession, and the provision of the necessary in-patient hospital treatment in order that this advice may be carried out. We have learnt that the provision of the first two parts was accepted in principle by the British Parliament 17 years ago. Our Ministry of Health has never ceased to consider the subject and to watch for a suitable opportunity to introduce these two services; on the other hand, it has never favoured any scheme of provision of in-patient treatment, primarily because of the prohibitive cost. The provision of laboratory aids to diagnosis and of specialist advice would not be of very great benefit to the insured person were there no arrangement whereby he could receive the necessary in-patient treatment that frequently must be the corollary of such advice. Fortunately in our country things have so evolved that the provision of in-patient treatment under any health insurance scheme has become unnecessary.

On April 1st, 1930, there came into force an Act introduced by Mr. Neville Chamberlain which did away with our ancient poor-law and in doing so transferred all the public hospitals to the care of the county councils. In doing this the Government of the day set out as the policy of the nation that these hospitals should be raised in their equipment and their efficiency to the highest possible standard; and the Government of to-day has shouldered the task of seeing that this is carried out. In the old days destitution was the criterion for admission to these hospitals and had to be proved by anyone applying for admission. Under the new Act "ad hoc" poverty is the criterion for admission and, considering the high cost of in-patient, surgical, and medical treatment there can be none who come under the National Insurance Acts who cannot make this claim.

When National Insurance is extended to the specialist services the man who pays his insurance money will already be paying for the upkeep of these institutions through the rates. He has already the right of admission into them. It is clear that he will not pay a second time towards them by his weekly insurance subscription.

The influence of health insurance upon hospital practice in the future therefore depends upon the extension of the benefit to specialist consultation and laboratory services. There is, however, another way in which insurance may be extended; and that is towards the dependents of the insured people. We may well assume that that has taken a place in our consideration of the future.

These consultations will be held in out-patient departments attached to hospitals or in new clinics specially organised and provided for them. The need for close association between out-patient and in-patient treatment will make it desirable that they should be held in clinics attached to in-patient hospitals. If all those who will come under National Insurance be removed from the present out-patient departments, the activities of these departments will practically have disappeared. At the clinic to which the insured person goes, he will claim that he be not kept waiting too long. At present the amount of time spent in waiting at an out-patient department is so great that many wage-earners cannot afford it. No attempt is as yet made, by organisation and appointment, to limit this time of waiting. When the insured person has paid by his subscription for his attendance, he will be able to insist upon an attempt being made to shorten his wait. He must not expect too much. It is impossible for a doctor to stick rigidly to a schedule; one patient may take him an hour, the next two or three may take but a quarter of an hour each; or, alternately, two or three successive cases may need each an hour's attention. The doctor who makes appointments at half an hour's interval and never gets behindhand is not usually a good doctor, and some degree of waiting must be expected towards the end of a session.

Next the insured person may claim that if the doctor in the out-patient department says he must come into the hospital, he should not be kept waiting unduly long. Some delay must happen in all but acute cases, but the long waiting-list of to-day, whereby some patients wait for a year or more, must become a thing of the past and the period of waiting be reduced to a month at the longest. Here again he may lose something by improved organisation. Speaking as a surgeon, I find that the long waiting-list, if used properly, is the finest sieve whereby to sort out those cases that really need operation from those in whom I have advised it unnecessarily. I find that those who fall to the bottom of the waiting-list and have been on it for more than six months include nearly all of the latter, and a further examination will often make me advise against the operation of which I had previously been in favour.

---

[2] On Compromise, Eversley edition, pp. 94, 95, and 99. London: Macmillan and Co.

The best way, however, of preventing operations being advised unnecessarily will be by the third point on which the insured person will insist: that is, that the amount of time allotted to the consideration of his or her condition shall not be less than a certain minimum. There is no more potent cause of operations being advised unnecessarily than a hurried examination. Again I speak with the experience of one in charge of an out-patient clinic where more persons attend than I can adequately treat. The minimum period will vary for each type of clinic and must be somewhat elastic, but within certain limits it will be necessary to keep to it.

These three demands my supposed worker will ask for his dependants as well as for himself; but the next applies to him (or her) only. It is that the clinics shall be held at an hour at which he can attend. This will mean the institution of evening sessions.

Next he may demand that if his complaint entails admission to hospital he shall be admitted under someone in whom he has confidence, who will usually be the physician or surgeon that he has seen at the out-patient clinic, or someone in close touch with him. This will mean that the out-patient department must be a part of the same institution as the in-patient clinic, not that it need be on the same site. It is probable that in big cities we shall evolve along the lines of out-patient clinics and admission blocks in the centre of the town with the in-patient hospital on the outskirts. The telephone and the ambulance have made it unnecessary to have the two together, but it is still necessary that the same doctors should be in charge of both. This question of keeping in touch will become more and more important as time goes on. The specialist must keep in touch with the general practitioner as well as with his brother specialists, and all with the various persons who carry out the treatment prescribed. To this end, members of the clerical staff must be attached to each out-patient clinic under the doctor in charge of it. Such an arrangement is already in existence in London in association with the care of school-children. It works very well indeed; and may be taken as an example from which a similar organisation may be planned for adult clinics.

The Question of Certification and the Education of the Student.

There is in England to-day an anxiety as to the finance of our National Health Insurance, because so many more people than previously are claiming sickness benefit. Of the various causes for this, one is said to be that doctors are not strict enough in the way in which they issue the medical certificate which is the key to this benefit. If this is so, it is very probable that the greatest abuse comes from certificates given in the out-patient departments of hospitals. I suggest that this problem may be solved by the authority that pays the sickness benefit providing the clerical staff to do the duties of liaison indicated above.

The treatment of the next generation depends upon the education of the doctors in this. Students before and after graduation cannot be taught unless there are patients about whom to teach. It is, therefore, in the interest of all that all should present themselves as cases for education. It is often suggested that when the people pay for their own treatment, instead of being dependent upon charity, they will resent being talked about. I do not believe this will be so. In an experience of teaching of a quarter of a century I have hardly ever found a patient who has objected to my teaching. Nurses, students, and personal friends who have been under my care have always been willing to allow me to exemplify my teaching by their condition. Private patients are always willing to be demonstrated to colleagues. There is no reason that any one should object if the teaching is kind; and it should be recognised that anyone attending a National Insurance out-patient clinic or going into any State or municipal hospital should do so on the understanding that they may be an object-lesson in teaching should the authorities think it necessary.

We have seen at every turn how the question of finance crops up. It must dominate all hospital administration in the future as it has done in the past. We may well say that the health of the nation is so important that no expense should be spared in maintaining it. That is so, but we must equally remember that there must be no waste. We have the contrast on the one side between expenditure and wasteful extravagance, and on the other between economy and stinginess. This struggle must always go on, and always the pendulum will be on the swing from one side to the other. So also with the pay of all concerned. The health of the individual cannot be treated purely as a business concern, and everyone who enters the service of the sick must be prepared to give more than is exactly in the bond. The labourer is worthy of his hire; but we must also remember the parable of the talents. We must be prepared to give account of what is entrusted to our care, or it will be taken from us. This must apply to the administrative staff as well as to the medical and nursing professions to an extent that perhaps is not realised enough.

These principles raise as matters of detail other problems. For instance, do we need two types of hospital to-day—the voluntary and the State? If we do, how is the work to be distributed between the two? If we do not, how are the voluntary hospitals to be absorbed under the State without a dislocation of their work? In our country insurance is national and any development must be on national lines. One thing only I demand: that is the care of the patient. So long as the treatment is good, he will not mind whether he goes into a hospital that is under the direct control of the central government, of the municipality, or of some individual organisation. This care will depend in the future upon efficient administration. The moment medicine passes from the hands of the individual to the team, administration becomes necessary. Administration means regulations, and these must be drafted to fit the diseases from which man suffers. His illnesses cannot be changed to fit the regulations. In carrying out these rules the widest elasticity must be allowed. No code can be drawn up to fit every person's illness. The doctor must be prepared to ride through every regulation in the interest of his patient if he thinks it necessary. In this he has a great responsibility, for if he fails to do so he may be brought to account. But when he does it he must justify his action and show good cause. The power to shoulder this responsibility is a necessary adjunct to his professional skill. Knowledge alone never made a good doctor. Character also is essential.

INSURANCE PRACTITIONER AND SICKNESS CLAIMS.

Referring to Memorandum 329/I.G. issued by the Minister of Health, summarised in our issue of June 13th (p. 1311) and commented on in our issue of June 20th (p. 1370), Dr. J. C. G. Dickinson (Braunton, N. Devon), writes: "There are certain important factors which largely vitiate the accuracy of the conclusions drawn by the Ministry from their figures. In the first place we are not informed as to the average period of sickness before reference by the approved society, nor of the degree of unemployment in the areas chosen for the compilation of statistics. In areas where unemployment is very great the tendency is to remain on the higher paid dole rather than to go on to the lower paid panel pay, and in these areas certification will tend to appear more satisfactory. No information is given of the number, if any, of cases referred to regional officers by panel practitioners, and of the results. It is agreed apparently on both sides that cases of great difficulty arise. I purposely avoid the term malingerer. But let it be asked: Have the regional officers been found capable of facing up to these very difficult cases? Personally I think not; and are they as negligible in effect as the Ministry appear to think? If one such case is let slip in every panel practice in the country, the total number may be small—some 20,000 in all—but their influence on fellow-patients is very great.

"What remedy is suggested? I suggest that regional officers might show greater courage in dealing with these very difficult cases. Further, when a panel patient referred by his society is found not to be incapable of work by the regional officer, or if the panel practitioner considers the man fit for work and the regional officer decides he is unfit, then in each case the patient be automatically removed from the list of the panel practitioner—the patient to have the right to apply to be retaken on the panel of the doctor concerned. In order to tighten up certification and maintain the standard of private practice it is necessary that the patient should have free choice of doctor, but also that the doctor should equally maintain the right to refuse or discard a patient."

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 20TH, 1931.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 62; scarlet fever, 1393; diphtheria, 877; enteric fever, 30; pneumonia, 566; puerperal fever, 46; puerperal pyrexia, 92; cerebro-spinal fever, 47; acute poliomyelitis, 6; encephalitis lethargica, 11; dysentery, 14; ophthalmia neonatorum, 109. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on June 23rd-24th was as follows: Small-pox, 138 under treatment, 2 under observation (last week 152 and 3 respectively); scarlet fever, 1101; diphtheria, 1409; enteric fever, 13; measles, 140; whooping-cough, 429; puerperal fever. 33 (plus 7 babies); encephalitis lethargica, 202; poliomyelitis, 2; "other diseases," 158. At St. Margaret's Hospital there were 14 babies (plus 6 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 2 (1) from enteric fever, 26 (0) from measles, 1 (0) from scarlet fever, 17 (5) from whooping-cough, 24 (3) from diphtheria, 38 (5) from diarrhœa and enteritis under two years, and 20 (3) from influenza. The figures in parentheses are those for London itself.

The fatal case of enteric fever outside London occurred at Sheffield. Only one death (under 1 year) from meningococcal meningitis was reported in London. Six deaths from measles occurred in Leeds, 4 in Sunderland, and 3 in Birmingham. Diphtheria claimed 3 victims each at Manchester and Rochdale.

The number of stillbirths notified during the week was 331 (corresponding to a rate of 48 per 1000 births), including 52 in London.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt. (Emerg.) R. Schofield to be Surg. Lt.-Comdr. (Emerg.).

The following appointments are notified: Surg. Comdr. E. C. Holtom to *London*; Surg. Lt. J. L. Cox to *Victory* for R.N. Barracks.

ROYAL NAVAL VOLUNTEER RESERVE.

The following appointments are notified: Surg. Lt.-Comdr. A. S. Bradlaw to *Victory* for R.N. Barracks; Surg.-Lts. R. M. Buchanan and J. F. Heggie (proby.) to *Frobisher.*

ROYAL ARMY MEDICAL CORPS.

Lt. S. M. Burrows to be Capt. and remains secd.

ARMY RESERVE OF OFFICERS.

Lt.-Col. R. C. Wilson, having attained the age-limit of liability to recall, ceases to belong to the Res. of Off.

Capt. W. S. C. Copeman from R.A.M.C., T.A., Res. of Off., to be Lt.

TERRITORIAL ARMY.

Capts. W. Baxter, G. V. Davies, and C. W. Dudley, to be Majs.

Capt. A. J. Will (late R.A.M.C.) to be Capt.

Capt. R. P. S. Kelman, New Zealand Medical Corps, to be Capt.

Lt. C. L. Broomhead to be Capt.

Lt. A. R. C. Higham, from 92nd (5th Lond.) Fd. Bde., R.A. (T.A.), to be Lt.

H. F. Wattsford (late Cadet, R.A.F.), to be Lt.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Capt. W. S. C. Copeman relinquishes his commn. on appt. to the Supp. Res. of Off.

INDIAN MEDICAL SERVICE.

Lt. (on prob.) B. Temple-Raston to be Capt. (on prob.) (prov.).

ROYAL AIR FORCE.

E. K. Pritchard is granted a temporary commission as a Flying Officer.

Flying Officer W. J. Cumming, relinquishes his short service commission on account of ill-health.

AUXILIARY AIR FORCE.

T. E. Cawthorne to be Flying Officer, No. 601 (County of London) (Bomber) Squadron.

MENTIONED IN DESPATCHES.

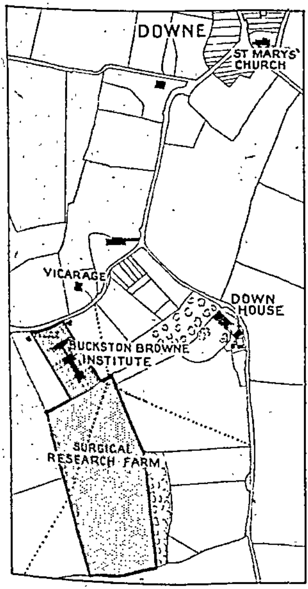
Maj. M. P. Power, R.A.M.C., has been brought to notice for distinguished services rendered during Operations on the North-West Frontier of India during the period April 23rd to Sept. 12th, 1930, by Field-Marshal Sir William Birdwood late Commander-in-Chief in India.

Opening of New Cottage Hospitals.—On Friday last week Prince George formally opened a cottage hospital at Newquay. The building is paid for but is not to be opened to patients until enough money is in hand for a year's working; for this another £500 is needed.—Also last week Lord Mildmay of Flete, Lord-Lieutenant of Devon, opened an extension of the Victoria Cottage Hospital at Sidmouth. The enlargement, which has cost £15,000, increases the number of beds from 14 to 30, including a small provision for paying patients.

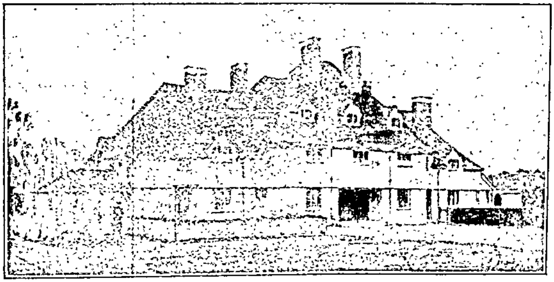
SPECIAL ARTICLES

THE BUCKSTON BROWNE SURGICAL RESEARCH FARM.

The foundation-stone of this research institute will be laid by Lord Moynihan at Downe, Farnborough, Kent, on July 8th, at 4 P.M. It will be recalled that early this year the Royal College of Surgeons of England received from Mr. G. Buckston Browne the means to build, equip, and endow a biological station in the country for the purpose of experimental surgical research. In this year's annual report on the museum of the College by its conservator, Sir Arthur Keith, an account is given of the way this benefaction, which will ultimately reach a sum of £100,000, is being spent. The site selected was one in the parish of Downe, Kent, adjacent to the grounds of Down House, where Darwin lived for 40 years. This house had previously been purchased for the nation by Mr. Buckston Browne as a memorial to Darwin and the acquisition of an adjoining site, for the biological station had the advantage of preserving the amenities of Down House. The site selected for the research farm is 16 miles from Charing Cross, and can be reached in 45 minutes by train and car. The institute to be built on this site is to provide (1) a series of suitable animal houses and huts; (2) experimental laboratories as efficiently and cleanly equipped as operating theatres of hospitals, with sick wards attached; (3) a residential block to provide accommodation for research workers and for the men in charge of the buildings and of the animals.



Sketch-plan showing the site of the Research Farm.



The Buckston Browne Surgical Research Institute.

Provision of comfortable residential quarters for the research workers is an essential part of the scheme, since it is believed that to bring together under a common roof a group of men, chosen from various hospitals and bound by a common object—that of advancing the resources of surgery—should do much to weld together the surgical enterprise of London and of the provinces. The residential block has been designed by Mr. E. C. Frere, F.R.I.B.A., on the lines of a Kentish farmhouse, and his design has been approved. The other parts of his plans—i.e., experimental laboratories and wards, and animal houses—are still under consideration. The buildings are to be as modest as is compatible with fulfilment of the purpose they are to serve, and as much as possible of the capital will be preserved to provide an income for the upkeep of the farm, and to furnish young surgeons with the equipment and material needed for their research. The supervision of the work carried on in the laboratories of the College and at the research farm will be entrusted to the conservator of the museum.

EPSOM COLLEGE.

An extraordinary general meeting of the governors of Epsom College was held on Friday last, June 26th, at the Royal College of Physicians of London, Viscount Burnham, President of the College, presiding. The object of the meeting was to consider, and, if thought fit, pass the following resolutions :—

That the Council of Epsom College be and is hereby authorised to promote legislation to amend, extend and repeal the provisions of the Royal Medical Benevolent College Act, 1855, and the Royal Medical Benevolent College Act, 1894, so far as may be requisite or convenient for the following purposes, that is to say :—

1. To effect the abolition of the present method of election of Pensioners, Foundation scholars and Annuitants by the governors of the College, and to substitute therefor election of Pensioners, Foundation scholars and Annuitants by a committee to be appointed by the Council and to consist of 20 governors, of whom ten shall be members of the Council and ten shall be governors (not being members of the Council) whom the Council shall select annually as most adequately representing the varied interests of the medical profession.

2. To provide for the extension of the benefits of the charity so as (*a*) to enable pensions to be provided for medical women (but not for their widowers unless such widowers are otherwise eligible) on the same conditions as

for medical men; (*b*) to render the sons of medical women eligible for election as Foundation scholars on the same conditions as the sons of medical men; and (*c*) to enable annuities or occasional pecuniary assistance to be provided for medical women or their families (but not for their widowers unless such widowers are otherwise eligible) on the same conditions as such annuities and assistance may be provided for medical men or their families.

The first resolution, revising the method of election, was proposed by Dr. Raymond Crawfurd, chairman of the Council, who said that Epsom College was administered under two Acts of Parliament, an Act of 1855, and an amending Act of 1894. By the 1855 Act it was decreed that the selection of beneficiaries should be by the governors, who in turn were the subscribers and donors. The purpose of this was to secure funds for maintenance. This, he said, had been done, but with a measure of success not adequate to the complete relief of destitution in the profession. "The Council have for years," he continued, "been anxious to abolish the voting system, and this spring decided to ascertain the views of the governors by circulation of a questionaire to all the 5500 of them. The result was that close on 93 per cent. voted for abolition; the percentage would have been much higher had it been practicable to give a detailed statement of the exact method of replacing the voting system. The reason why the Council have not taken action before is that they could not face the expense of passing a private Bill through Parliament." This difficulty had been surmounted, he added, by the very friendly attitude of certain public Departments who have undertaken jointly to submit to Parliament the necessary legislative changes as part of their annual parliamentary scheme. Admitting that the Council had been anxious as to the amount of pecuniary support they would lose by the abolition of the general vote, Dr. Crawfurd added that they believed their loss would be small, and even hoped that the more democratic method for the selection of beneficiaries in future would attract a larger number of supporters. If the resolution were passed the selecting body, he said, would be ten members of the Council and ten governors not members of the Council; they would be appointed, as a rule, by other medical bodies at the invitation of the Council, and all parts of the country successively would obtain a direct voice.

The resolution was seconded by Dr. H. B. Brackenbury, and was passed unanimously.

Dr. Crawfurd then proposed the second resolution which would provide for the extension of the benefits of the Foundation to women on the same terms, with one reservation, as those now enjoyed by men. He pointed out that the exclusion of medical women and their children from the benefits of the Charity was due to the fact that in 1855 medical women did not exist in this country, and in 1894 they were still looked at askance. But with women admitted to the profession on equal terms with men it became manifest that their exclusion was an anomaly and an injustice. Such was the change in the position of medical women by 1931 that the proposal for the inclusion of them and their children in the benefits of the Charity was carried by a unanimous vote of the Council.

The resolution was seconded by Dr. Brackenbury, and here also a unanimous vote was recorded by the meeting.

ELECTIONS.

The following were the results of the annual elections which were announced at the annual general meeting which immediately preceded the extraordinary meeting:—

Pensionerships.

	Votes.
Marin, Mrs. Edith M.	3523
Shortridge, Mrs. Louisa	3407

* Hadlow pensioner. † Ordinary pensioner.

"Morgan" Annuity.

	Votes.
Waring, Miss S. Annette	3342

Foundation Scholarships.

	Votes.
Ring, Charles A. S.	12,436
Hyde, Edward K.	10,856
Purnell, James A. W.	10,672
Smith, Hugh F. S.	10,411
Evans, Raymond F. G.	9614
Reid, Alexander P.	8308
Walker, Robert G.	7075
Armitage, Raymond S.	5738

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

PASTEURISATION UPHELD.

THE tendency to question the full nutritional value of pasteurised as compared with raw milk, shown in Prof. Stenhouse Williams's letter to your columns,[1] is evident also in this country but has not received official encouragement. The conference of State and Provincial Health Authorities of North America, which met recently in Washington, heard a report from its committee on milk, which roundly affirms the continued belief of health authorities in America that pasteurisation has no significant deleterious effect upon the nutritional value of milk. In the first place the report of the committee on milk production and control of the White House conference is endorsed as being the result of "an extended study and investigation of all phases of milk in its relation to the public health." The latter report states[2]:—

> Health authorities should recommend to American milk consumers that the general market milk be pasteurised before it is consumed, either in a properly supervised pasteurisation plant or at home.

The health officers' committee then proceeds to take up two recently published papers which appear to discredit pasteurisation and to criticise them in detail. The second of these papers is the article by Mattick and Golding, published in your columns on March 21st (p. 662). The committee states that these authors' conclusions are not justified by the experimental results, the difference in weight gained between the animals fed with heated and raw milk being, in its opinion, too small to be significant. The committee then presents abstracts of research, including that reported by Dr. Janet E. Lane-Claypon to the Local Government Board, which seems to show that heating milk does not destroy its nutritive value. The committee is anxious that further research of an authoritative character be undertaken, especially upon the effects of feeding raw and pasteurised milk respectively to young of the human species. It seems that during last year 39 epidemics in North America were traced to milk-borne infection. Only one of these was attributable to pasteurised milk, the milk in this case having been infected by a carrier after pasteurisation.

NEW YORK MUST BURN ITS GARBAGE.

For many years New York City has disposed of its garbage by loading it into scows which are then towed out to sea and the garbage dumped some forty miles from the shore. Even so it is not wholly lost, and New Jersey's coastal resorts have suffered by the drift borne upon them by shoreward winds and tide. The State of New Jersey summoned the City of New York before the Supreme Court. The defence of the city was a plea that the garbage was being dumped beyond the three-mile limit. This defence was set aside by the court as "of no importance." The court has now ruled that New York must stop dumping garbage at sea within a "reasonable time." Plans are being pushed forward for the building of 15 new garbage incinerators at an estimated cost of over 17 million dollars. The cost of incinerating garbage in this country varies from 26 cents per ton at Florence, S.C., to 5 dollars per ton at Providence, R.I. The cost of dumping garbage at sea has been only 23 cents per ton.

THE COFFEY-HUMBER CANCER CURE.

Not long ago Dr. W. B. Coffey and Dr. J. D. Humber were presented by a wealthy New York lady with an estate on Long Island whereon to erect a cancer research laboratory. The New York Board of Social Welfare has given them permission to have a laboratory there on condition that they treat no patients with adrenal cortex extract. The Californian doctors are apparently not satisfied to have a laboratory on these terms. Their lawyer is expected to ask the Welfare Board for a new hearing.

CORRESPONDENCE

A MATERNITY SERVICE.

To the Editor of THE LANCET.

SIR,—On reading the letter of Prof. F. J. Browne (p. 1422) one wonders where he gained his comprehensive knowledge of municipal hospitals. As one responsible for the work of a municipal general hospital, in which the council proposes to build a new and enlarged maternity department to replace the existing one, I must feel an object of attack by Prof. Browne. I do not regard the policy of the council as "utterly reactionary" but, on the contrary, as an important step towards safer midwifery. On the present staff "really trained and efficient people" are available, grading down from the visiting obstetrician—a university clinical lecturer and a Fellow of the Royal College of Surgeons, England—who is in complete clinical charge; through the senior resident obstetrician—a Fellow of the Royal College of Surgeons, Edinburgh—who, prior to his appointment had been for over two years senior resident and obstetric tutor in a teaching maternity hospital; to the ordinary resident medical staff, who come to the maternity department after periods in the medical and surgical wards. The staff carries on a tradition of successful midwifery of many years' duration. In 1930 there were 1453 confinements.

The teaching of midwifery is not perfect. One dislikes to use the tu-quoque in controversy, but sometimes it is argument. Has Prof. Browne never known of the appointment to the honorary staff of a voluntary hospital of a man or woman who has never filled a resident position in a maternity hospital, and is it not significant that Dr. Bethel Solomons should think it necessary[1] to warn the general practitioner that when he wants a consultant on midwifery he should find out if the latter is really a practising obstetrician? The attempt to divide doctors into "municipal" and "voluntary" is rather ridiculous. All doctors have worked at some time in voluntary hospitals, and most of them are willing to accept service under a municipality. One type of hospital does not command a monopoly of expert knowledge and skill.

We seem to be quite agreed that the proper place for a maternity hospital is in a department of a general hospital. No doubt we shall continue to differ on the question as to whether it is to be under municipal or voluntary management. This point will probably be decided by local conditions. I am confident that under municipal control there will be no difficulty in securing an efficient staff, and that this staff will be willing and able to do its part in the training of future consultants as well as of general practitioners.

I am, Sir, yours faithfully,

HENRY H. MACWILLIAM,

Medical Officer, Walton Hospital, Liverpool.

June 29th, 1931.

FATIGUE IN THE CINEMA.

To the Editor of THE LANCET.

SIR,—With reference to Mr. Savin's article on this subject in your last issue (p. 1433), in my experience the chief discomfort has been due to the relative lighting in the stage and auditorium. When the auditorium is very dark many suffer with headaches and discomfort, which is entirely removed when the auditorium is better lighted. The same can be noted in a card-room. When the room is lighted by lamps over each small table many will complain of headaches, which cease when a large central light is used as well. In both these cases the trouble is caused by defective stimulation of the periphery of the retina.

I was consulted by a patient who had been mountaineering for a month in Switzerland. On returning to his office he found that he had the greatest difficulty in reading, though he concentrated the light upon his work. He was completely cured on being told to have the remainder of the room as brightly illuminated as possible.

There is no evidence that the rods are percipient elements, but all the facts point to the conclusion that they are the nerve elements regulating the sensitiveness of the photo-chemical film.

I am, Sir, yours faithfully,

F. W. EDRIDGE-GREEN.

Board of Trade, June 27th, 1931.

SYPHILIS AND YAWS.

To the Editor of THE LANCET.

SIR,—Space would not permit me to give the entire "dozen ways" of showing the ancient European ancestry of syphilis. I will refer to one direct and one indirect method of proof.

A. Corn. Celsus (30 B.C.–A.D. 38), Lib. VI., XVIII., 2, speaking of the genital organs and specifically of phimosis, says, in part, "after overcoming the resistance of the prepuce" (one may almost sense the reduction en bloc) "there are seen ulcers that are situated upon the glans, or the prepuce, or on the penis beyond the glans, some of these are clean and dry while others are moist and purulent." Now the only common ulcers of the genitals that are clean and dry are Hunterian chancres, and the only ones that are moist and purulent are chancroids and mixed infections. (See E. Lancereaux "A Treatise on Syphilis," vol. i., p. 13.)

---

[1] See THE LANCET, June 27th, p. 1384.

Knowing that the Greeks called what we name flat condylomata by their word for fig, σῦκον, and that the Romans simply translated this into *their* word for fig, "ficus," and used it for the same lesions, we turn now to the same Roman author, Celsus, Lib. VI., III., and, admitting that none of the ancients knew the connexion between genital lesions and constitutional disease, may read with understanding the author's words on sycosis. "There are also ulcers similar to fici called by the Greeks σύκωσις. The flesh overgrows: this indeed is usual. Under this are two varieties. One ulcer is hard and round; the other moist and irregular. From the hard one a sticky material exudes: from the moist more and of a bad odour. Both may be in those parts covered by hair but the hard round variety usually comes on the beard, the moist generally on the scalp." There is much more here than barber's itch and kerion Celsi. The fact that the author uses to describe these face lesions the same term "fici" as was in general use at that time to define condylomata between the nates shows that he was describing a condition quite well known to "us tropical frambœsiologists." In this connexion see "The Epigrams of Martial" (Lib. VII., 71), in which the author pokes fun at his victim with a play upon the word "ficus." Martial (43–104) was a layman and not bound by the medical ethics of his day.

Now for the item of inductive proof. At the present time it is recognised that aneurysm requires for its production the special type of mesarteritis produced by *Treponema pallidum* alone. This applies to arteries with lumina no greater than 1 mm. in diameter. Ligation for aneurysm has been a common practice since the time of Galen (131–201). Garrison in his admirable "History of Medicine," fourth edition, page 109, says in connexion with ligatures for this and other surgical purposes that there was a special shop on the Via Sacra where they were to be bought. Antyllus, a contemporary of Galen, perfected a technique for the ligation of aneurysm which held the field down to the time of John Hunter (1786). Da Costa recommends the Antyllus method for certain aneurysms even at the present time.

Now if the Romans showed enough aneurysms to make it possible for surgeons to develop such a worthy technique of cure as that of Dr. Antyllus it seems reasonable to think that *Treponema pallidum* was getting into their blood *somehow*, and it is our firm belief that it was through the "clean dry genital ulcers" described by Celsus.

I am, Sir, yours faithfully,
C. S. BUTLER,
Washington, D.C., June 4th, 1931. Capt. (M.C.), U.S. Navy.

To the Editor of THE LANCET.

SIR,—It must be obvious that there is little to be gained by further correspondence upon this subject; the problem is too big a one to thrash out in these columns. Any reader of THE LANCET who has the time and opportunity of studying the literature of the subject *and* the diseases themselves, with care in interpreting the terms used and in deciphering the sequence of manifestations, and with due regard to the sources whence the older writers derived their information and to the general trend of medical opinion of their times, must form his own opinion. He may find himself unable to come to a definite conclusion in regard to the relationship of yaws and syphilis, but I have little doubt he will agree with me that sibbens (and other outbreaks of disease mentioned by me in a previous letter) was certainly not yaws, but was epidemic, for the most part non-venereal syphilis, not always non-sexually acquired as Dr. Burke asserts.

I must, however, allude to a previous letter by Captain Butler to correct a statement which he makes in regard to my criticism of Lancereaux, an eminent syphilologist who had never seen yaws. I had said "Lancereaux was not even aware that *pian* and *yaws* referred to the same lesion." Lancereaux's words are: "There afterwards appear in different parts of the body, in pian little red pimples, in yaws papules and pustules, which soon became covered with uneven crusts beneath which are more or less extensive ulcers"—thereby distinguishing wrongly, pian from yaws, though grouping them together as belonging to the domain of syphilis, this idea being based upon the garbled accounts of frambœsia he had received and the false belief that the disease was transmitted hereditarily. I suggested that Captain Butler had been unhappy in the sources of his inspiration in regard to yaws. Later he has cited Huxham, Sydenham, and Buchan as "aware that yaws was simply non-venereal syphilis." Does Captain Butler really subscribe to such a view? Has anyone in this country seen an extra-genital chancre followed by a typical eruption of yaws? May I take this opportunity of asking any of your readers who has at any time under his observation a case of syphilis exhibiting what has been termed a frambœsiform syphilide, to give me the opportunity of seeing the case.

Captain Butler has also been unfortunate in following Jonathan Hutchinson in his opinion in regard to the case reported in THE LANCET thirty years ago. Hutchinson was guilty in just the same way as older syphilologists, as was pointed out by Patrick Manson in the discussion. I think I might go further and suggest that Captain Butler appears to have been equally unfortunate in his clinical material. In a recent paper (International Clinics, 1930, vol. ii.), he figures a Javanese child exhibiting (let me say for the benefit of those unacquainted with yaws) the *common* absolutely typical eruption of frambœsia; but his own note about the case reads: "This is what is called for by text-books in their definition of yaws, but is rarely seen." If Captain Butler will study the disease in Africa or the Dutch East Indies he will be surprised to see the disease, apparently unfamiliar to him, as recognised and described by clinicians as a clinical entity, whatever its relationship to syphilis may prove to be in the future. He will then understand why I suggested that the "dualists" would have good reason in throwing the onus of proving them wrong upon Captain Butler, a suggestion which appears to have caused him pain.

I am, Sir, yours faithfully,
Wimpole-street, W., July 1st, 1931. HUGH S. STANNUS.

ACUTE RHEUMATISM FOLLOWING TONSILLITIS.

To the Editor of THE LANCET.

SIR,—I have read with especial interest Dr. Sheldon's paper in your issue of June 20th (p. 1337). It is of enhanced value in that the observations were all made on children already in hospital and who were therefore under close supervision the whole time.

The conclusions agree very closely with those of previous workers. A point of great interest is the so-called silent period between the previous sore-throat and the subsequent attack of rheumatism. This was first pointed out in your columns [1] by Dr. J. M. H. Campbell and myself, when we found the period to be 5 to 25 days, the majority falling 7 to 14 days after the initial tonsillitis. This has been confirmed by Dr. B. Schlesinger [2] who demonstrated a period of 10 to 21 days, and now by Dr. Sheldon who found a period of 9 to 25 days. The period seems to me to be of very great importance as it bears largely on the ætiology of rheumatism. Dr. Sheldon and Dr. Schlesinger believe this is a period of sensitisation, and to quote Dr. Schlesinger's words "the rheumatic patient is in a hypersensitive state from the tenth to the twenty-first day after the antigenic throat infection, at any time during which a reaction in the form of acute rheumatism is liable to occur," comparable to the sensitisation produced by a dose of serum with its subsequent fever, rashes, and joint pains. Dr. Sheldon now goes a stage further and states "that the rheumatic reaction, whether arthritic or cardiac, has no more claim to be considered infectious than has, for example, post-diphtheritic paralysis." I am sure this is an unwarranted conclusion. A patient with no previous heart disease, or with old quiescent disease, develops a severe carditis 9 to 25 days after tonsillitis, as Dr. Sheldon himself admits. Surely he does not suggest that this is not of infectious nature. There is no evidence of this type of reaction after serum, and anyone who has seen the vegetations on the heart valves and compared them with subacute bacterial endocarditis cannot fail to see the resemblance between the two.

This same silent period can occur after other infectious diseases of childhood. Dr. Schlesinger found a similar silent period between the initial sore-throat of scarlet fever and the onset of scarlatinal rheumatism, and in our original paper we quoted cases of rheumatism following after a silent period, after scarlet fever (five cases), pneumonia (five cases), chicken-pox (two cases), measles (three cases), &c. In other words, rheumatism can occur after any illness liable to produce a state of lowered resistance in the child; and tonsillitis is one of the commonest and most neglected causes of this. In this connexion the work of Dr. A. Osman on scarlatinal nephritis seems of particular value. Working with Dr. Close, he has shown[3] that after an attack of scarlet fever there is a lowered alkali reserve in the blood which reaches its lowest limit on the twentieth day after the initial sore-throat, that is at the same time that scarlatinal nephritis sets in. It appears that in cases in which this fall in alkali reserve is small the nephritis is absent, and if it be prevented by giving enough alkali, the incidence falls from 4·7 per cent. to 0·4 per cent. There is also a fall in alkali reserve following tonsillitis, although this factor does not seem to be of especial importance in rheumatism.

I am sure that if we can obtain an insight into the biochemical factors associated with the lowered resistance of the patient during this silent period, we should go a long way towards preventing the onset of rheumatism. Probably the present system of treating a patient with tonsillitis by keeping him away from school for only two to three days contributes to the onset of acute rheumatism and any rheumatic patient who develops tonsillitis should be considered a sick person for at least three weeks.

I am, Sir, yours faithfully,

E. C. WARNER.

Devonshire-place, W., June 20th, 1931.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS.

HEALTH SERVICES IN SCOTLAND.

ON Thursday, June 25th, the House of Commons went into Committee of Supply on the Scottish Estimates. Sir R. YOUNG, Chairman of Committees, was in the chair.

Government's Statement.

On a vote of £1,607,203 for the salaries and expenses of the Department of Health for Scotland, Mr. W. ADAMSON (Secretary of State for Scotland) said the largest item in the estimates was that for housing, which was 65 per cent. of the total. Since the State subsidy was introduced in 1919 a total of 121,019 houses had been built with State assistance up to May 31st this year. The shortage of houses still remained somewhere about 100,000, so that they had a long way to make up before the people of Scotland could be said to be reasonably housed. Ever since the present Government came into office a steady endeavour had been made to stimulate local authorities to renewed housing activity, and to restore the confidence which had been destroyed by the action of the late Government in reducing the State subsidy. Those efforts were now meeting with some measure of success, but no one could rest satisfied with the present situation. Representatives of the local authorities had been interviewed with the object of securing further progress, but unfortunately a number of local authorities had failed to appreciate the need for improved housing, even when in some cases it had been urged upon them by their officials. Parliament had vested the Central Department with power to step in where a local authority failed to do its duty, and it was well for him to speak frankly on this matter. He had given definite instructions to the Department that further pressure was to be applied, and, if necessary, compulsory action taken against the defaulting local authorities. If the 47 local authorities who had not yet submitted statements under the Act of 1930 made provision adequate to the needs in their areas he thought they could look forward to an average of something like 20,000 houses a year for the next three years. This would make a very substantial contribution to the rehousing of the Scottish people.

DROP IN SICKNESS BENEFIT.

The outstanding fact about the work of the National Health Insurance Scheme during 1930 was perhaps the drop in payments for sickness and disablement benefit. The amount paid out by the approved societies was less per member than in any year since 1925. The continued unemployment, which was affecting the income of approved societies from contributions, affected the relief coming from reduced expenditure on sickness benefits. In any effort to stop leakage of funds the utmost care must be taken that sick persons got the benefit to which they were entitled, and that they were also provided with the medical advice and attendance that they required at the proper stage. During 1930 some new forms of medical records were introduced and a system by which the Department would receive details of all sickness among insured persons. Sufficient time had not elapsed in which to compile complete results which would justify some generalisation. The preliminary reports which had been published in the annual report of the Department were merely tentative and should be read as no more than samples of the kind of information and sickness statistics that the Department would be able to furnish once this new scheme was in complete working order.

THE CHANGE OVER.

The change in the administration of the poor-law under the Local Government Act, 1929, took effect on May 15th, 1930. In the administrative schemes which the new Act required the local authorities to submit for his approval the majority provided that assistance in the form of maintenance and treatment of mental defectives, provision for the health of expectant mothers, nursing mothers, and children under 5, the care of blind persons, and provision for the feeding, clothing, and treatment of school-children would be taken out of the poor-law. Progress was being made in many areas in Scotland to improve and extend water-supplies and drainage facilities. Dealing with the medical services, Mr. Adamson said that measured by the death-rate, 1930 had been a very healthy year. Although some death-rates had risen—cancer for example, some infections and maternal mortality very slightly—the local death-rate was only 13·2 in 1930 compared with 14·5 in 1929. The deaths of infants were 83 per 1000, lower than the recorded rate for any year with the exception of 1923, which was 78·9. The tuberculosis death-rate was also very satisfactory—88 per 100,000 compared with 94 in 1929. This rate of 88 compared with 124 per 100,000 in 1920—a very fine achievement. For the first time since 1920 the birth-rate had increased. The possible harm that the continuance of unemployment might do to the health of the people had been a real cause of anxiety not only to the Department, but to many others who took a keen interest in the health and welfare of the people. During 1930 the Department, on his instructions, carried out a special investigation involving over 100,000 school-children in Edinburgh, Glasgow, Dundee, Aberdeen, and Lanarkshire, and its results seemed to justify the broad conclusion that the social services were warding off the worst effects of this period of difficulty. The report of the investigation would be published. Although on many points the material for drawing conclusions was slender, the figures showed that on the whole, on beginning school life, and even on leaving school, children were now better clothed, were cleaner and suffered less from malnutrition, rickets, and defective teeth. That meant a positive advance in the capacity of the citizens of the future.

ADEQUATE HOSPITAL SERVICE.

Another subject to which the Government were devoting special attention was the development of an adequate hospital service in respect of beds, buildings, and quality of service. It was an urgent problem, and now that the local authorities had had a year since they took over the duties of parish councils, and were invested with the new powers conferred upon them, they would be expected to go forward with a policy which would at least end the old and inexcusable differentiations between the standard of treatment in poor-law hospitals and that in, say, fever hospitals, or in the ordinary voluntary general hospitals. There should be only one hospital standard which would be open to all. The estimate for investigations concerning the causes of diseases had been increased this year from £100 to £2500. It was intended that the scientific advisory committee would guide these investigations, and he looked for a large return from this proposed small expenditure. There were some people—and they were particularly vocal at present—who criticised the social services and spoke and wrote glibly of cutting them down, but he thought that the condition of the country would be wretched indeed if it could not maintain the services for which these estimates provided and which were fundamentally necessary in a civilised State.

Criticisms of the Statement.

Sir J. GILMOUR said he hoped that when next they came to discuss these estimates the Secretary of State for Scotland would be able to tell them exactly what progress had been made with slum clearance under the Act of 1930. He was glad that the right hon. gentleman and his Department, speaking with authority, admitted that in the main the changes which had taken place under the Local Government Act, 1929, appeared to be advantageous. He agreed with Mr. Adamson that one of the most important things to-day was to see that the health treatment of those who came under the poor-law should be on a different and better footing than in the past. One of the first and most elementary steps to bring that about was the step taken under the Local Government Act. He welcomed the announcement that there would be a continuous effort to coördinate scientific research in health matters in order that the results of the scientific research might be brought quickly to the notice of local doctors, and those who had to deal with the problems of health at first hand. He urged the Secretary of State to increase and improve the health services in the great cities and in the outlying parts of the country where men and women were working with devotion and skill—such as, for example, the hospitals in Orkney and Shetland, and in the Hebrides.

THE NEW MACHINERY.

Mr. SCOTT said one of the most satisfactory parts of the report of the Department of Health was that which showed that tuberculosis was being stamped out. There was, however, one less satisfactory set of figures—namely, those in regard to infectious diseases. The average number of cases of enteric fever over a period of ten years was 535, whereas in 1930 the figure was as high as 766. The average figure for diphtheria over a period of ten years was 8907, whereas the figure for last year was 11,580. He would like to have an explanation of these alarming increases. It had been suggested that the cause might be impure water supply, and he would like to know whether the Department endorsed that view. He reserved his judgment in regard to the change in machinery under the Local Government Act. He was far from being satisfied, notwithstanding what the report of the Department of Health said, that the changes in regard to the poor-law would be permanently beneficial. He was afraid that there had been thrown upon the scrapheap a vast number of experienced men and women who had formerly given their expert services to the administration of the poor-law. He questioned whether, to a large extent, the new machinery was not even now breaking down. The work was being handed over more and more to paid officials. It was very desirable that there should be some inquiry into the working of the new Act, and he hoped that a commission would soon be appointed for that purpose.

BLACK PATCHES.

Mr. R. W. SMITH said, on the whole, there was a marked improvement in the vital statistics of Scotland, but there were still one or two black patches which could be removed by administrative methods. One of these was maternal mortality, which was rather distressing, because more care was taken of expectant mothers and of the children than ever before. Yet unfortunately the mortality figures were not falling as they ought to do. The Secretary of State had informed the Committee that new forms of medical record were to be instituted in the case of sick persons and he (Mr. Smith) suggested that they should also be supplied in cases of maternal mortality. The great trouble arose from puerperal sepsis, and it seemed to him that by greater care something could be done to prevent the frequency of such cases.

The report of the Department of Health stated that these cases might be prevented if doctors, midwives, and maternity nurses were to make a wider use of masks and adopt more careful antiseptic treatment for the hands. It was also suggested that in hospitals there should be bed isolation by means of metal and glass screens. If the statistics of maternal mortality were classified into smaller groups they would be able to note the number of deaths in institutions, the number of deaths in the patients' homes attended by a nurse or by a doctor, and the number, where patients were nursed in their own homes, attended by a midwife. That would give them some idea where the poison came from. A country doctor had informed him recently that he found that fever cases went wrong in the cottages than in nursing homes. It was his opinion that the septic germ was not in the cottages but in the nursing homes, and that there was more likelihood of the germ being passed from one patient to another in institutions and nursing homes than in cottages where there were clean and healthy conditions, and the germ did not exist. He thought there was a large amount of reason in that. In the matter of medical attention the new Local Government Act was extraordinarily useful, because it coördinated all the medical services from birth until the child was of school age. Something more, however, might be done in looking after the children between the ages of 1 and 5 years, because the report stated that children were fairly well looked after up to one year.

HARDSHIP IN THE HIGHLANDS.

Mr. MACPHERSON said in the rural parts of Scotland the population was very sparse and often a doctor lived 20 to 25 miles from some of his patients. He asked whether the Department of Health was assisting or intended to assist the sparsely populated localities, where it was difficult to get the minimum number of telephone subscribers, to get a telephone service installed so that the poorest people might be brought into quick touch with a doctor. He had had case after case brought to his notice of a patient dying, or being driven almost to the point of death, because it took half a day to get into touch with a doctor. The local medical practitioner in the Highlands was very often a man of great skill in medicine and in surgery. In his tours through the Highlands he often went into doctors' houses, and he found that what was specially needed was a small additional room where patients might wait, or which, in an emergency, might be used even for a slight operation. If the Secretary of State would consult his medical advisers they would agree that an extra room of this kind in the doctor's house was greatly needed.

Mr. MACQUISTEN supported Mr. Macpherson's plea for greater telephone facilities throughout the Highlands and Islands of Scotland. He wished that the Secretary of State would impress on his medical officers the need for preventive methods. The dental deterioration in the younger generation to-day was entirely due to unsuitable foods and the sophisticated. devitalised and preserved stuff which the people now ate.

Mr. McGOVERN said Mr. Macquisten had mentioned the great amount of ill-health due to tinned foods and white bread. The real trouble, however, was that the people were often not able to consume any decent food whatever. Bad housing and overcrowding, especially in the industrial areas, was one of the greatest factors together with malnutrition contributing to ill-health among the population of Scotland. If they were going to improve the health of the people in the slums, the rents of the new houses must be the same as those from which the slum-dwellers were taken.

DEPRESSION IN TRADE.

Major ELLIOT said they found from the report of the Department that a section taken out of the 1,850,000 insured persons in Scotland showed a lower morbidity-rate this year than in previous years, and that was a matter upon which they ought to congratulate themselves. One of the important factors in this connexion had been the absence of an influenza epidemic such as those which had repeatedly occurred in previous years. That was one of the important reasons for the drop in the payments of sickness benefit. The tuberculosis returns were one of the most obvious ways of telling whether the public health was good or bad, and the figures had fallen to a point never touched before. Infantile mortality had also fallen to a point never reached before. The special inquiry by the Department of Health into the health of the children of unemployed persons showed that they were not suffering. Indeed, the health of the people of Scotland was being maintained remarkably well. But the lesson of this report was that depression in trade and industry were the things that were really holding back the country from the progress which they desired it to make.

Government's Reply.

Mr. WESTWOOD (Under Secretary of State for Scotland), replying to the debate, said that Dr. Smith, of the Aberdeen Health Department, had been awarded the Nichols Prize of the Royal Society of Medicine, which was given every three years, and he had given the Government very valuable assistance in connexion with medical research. With regard to enteric fever and diphtheria the investigations of the Department of Health had shown, unfortunately, that it was most difficult to trace the source of infection, but they were continuing their investigations. If there were any particular cases of lack of telephone facilities in sparsely populated areas to which Mr. Macpherson desired to draw particular attention they would be inquired into and, if it was possible, assistance would be given. The question of an additional room in doctors' houses seemed to be quite worthy of consideration, and would be looked into by the Department.

CARE OF MATERNITY.

The Duchess of ATHOLL drew attention to a matter which was insufficiently emphasised in the report—namely, the extension of the maternity and child-welfare schemes in the rural areas. There might be many reasons for maternal mortality, but all medical opinion was agreed that one of the chief reasons was the want of more antenatal care. The presence in these districts of nurse health visitors would be a very important factor. The report brought out the need for antenatal care from the point of view of the health of the newly born child. Only one-third of the mothers of Scotland received antenatal care, and that was not at all a satisfactory position. One of the first things to be done for health in Scotland was to ensure that every county possessed a district nursing association.

Miss LEE said she was very troubled by the following statement which she found in the report of the Department of Health: "Maternity homes are intended for normal confinements but, owing to the shortage of maternity hospital accommodation, they have been used to some extent for abnormal cases, for which, however, they are neither adequately equipped nor staffed." She felt bound to bring this point again before the Committee, because women in her own constituency had complained that there was a scarcity of hospital places in the west of Scotland for abnormal cases where there were particular medical difficulties present. She thanked the Secretary of State for the work he had done for nurses. She had brought to the right hon. gentleman's notice cases where nurses in public institutions were being underfed and certainly overworked. She begged that the good work which the right hon. gentleman had begun in this matter should be continued. There was great need for its continuance because she was far from satisfied with the condition of things in the voluntary hospitals.

The vote was withdrawn.

sickness among insured persons. Sufficient time had not elapsed in which to compile complete results which would justify some generalisation. The preliminary reports which had been published in the annual report of the Department were merely tentative and should be read as no more than samples of the kind of information and sickness statistics that the Department would be able to furnish once this new scheme was in complete working order.

THE CHANGE OVER.

The change in the administration of the poor-law under the Local Government Act, 1929, took effect on May 15th, 1930. In the administrative schemes which the new Act required the local authorities to submit for his approval the majority provided that assistance in the form of maintenance and treatment of mental defectives, provision for the health of expectant mothers, nursing mothers, and children under 5, the care of blind persons, and provision for the feeding, clothing, and treatment of school-children would be taken out of the poor-law. Progress was being made in many areas in Scotland to improve and extend water-supplies and drainage facilities. Dealing with the medical services, Mr. Adamson said that measured by the death-rate, 1930 had been a very healthy year. Although some death-rates had risen—cancer for example, some infections and maternal mortality very slightly—the local death-rate was only 13·2 in 1930 compared with 14·5 in 1929. The deaths of infants were 83 per 1000, lower than the recorded rate for any year with the exception of 1923, which was 78·9. The tuberculosis death-rate was also very satisfactory—88 per 100,000 compared with 94 in 1929. This rate of 88 compared with 124 per 100,000 in 1920—a very fine achievement. For the first time since 1920 the birth-rate had increased. The possible harm that the continuance of unemployment might do to the health of the people had been a real cause of anxiety not only to the Department, but to many others who took a keen interest in the health and welfare of the people. During 1930 the Department, on his instructions, carried out a special investigation involving over 100,000 school-children in Edinburgh, Glasgow, Dundee, Aberdeen, and Lanarkshire, and its results seemed to justify the broad conclusion that the social services were warding off the worst effects of this period of difficulty. The report of the investigation would be published. Although on many points the material for drawing conclusions was slender, the figures showed that on the whole, on beginning school life, and even on leaving school, children were now better clothed, were cleaner and suffered less from malnutrition, rickets, and defective teeth. That meant a positive advance in the capacity of the citizens of the future.

ADEQUATE HOSPITAL SERVICE.

Another subject to which the Government were devoting special attention was the development of an adequate hospital service in respect of beds, buildings, and quality of service. It was an urgent problem, and now that the local authorities had had a year since they took over the duties of parish councils, and were invested with the new powers conferred upon them, they would be expected to go forward with a policy which would at least end the old and inexcusable differentiations between the standard of treatment in poor-law hospitals and that in, say, fever hospitals, or in the ordinary voluntary general hospitals. There should be only one hospital standard which would be open to all. The estimate for investigations concerning the causes of diseases had been increased this year from £100 to £2500. It was intended that the scientific advisory committee would guide these investigations, and he looked for a large return from this proposed small expenditure. There were some people—and they were particularly vocal at present—who criticised the social services and spoke and wrote glibly of cutting them down, but he thought that the condition of the country would be wretched indeed if it could not maintain the services for which these estimates provided and which were fundamentally necessary in a civilised State.

Criticisms of the Statement.

Sir J. **GILMOUR** said he hoped that when next they came to discuss these estimates the Secretary of State for Scotland would be able to tell them exactly what progress had been made with slum clearance under the Act of 1930. He was glad that the right hon. gentleman and his Department, speaking with authority, admitted that in the main the changes which had taken place under the Local Government Act, 1929, appeared to be advantageous. He agreed with Mr. Adamson that one of the most important things to-day was to see that the health treatment of those who came under the poor-law should be on a different and better footing than in the past. One of the first and most elementary steps to bring that about was the step taken under the Local Government Act. He welcomed the announcement that there would be a continuous effort to coördinate scientific research in health matters in order that the results of the scientific research might be brought quickly to the notice of local doctors, and those who had to deal with the problems of health at first hand. He urged the Secretary of State to increase and improve the health services in the great cities and in the outlying parts of the country where men and women were working with devotion and skill—such as, for example, the hospitals in Orkney and Shetland, and in the Hebrides.

THE NEW MACHINERY.

Mr. **SCOTT** said one of the most satisfactory parts of the report of the Department of Health was that which showed that tuberculosis was being stamped out. There was, however, one less satisfactory set of figures—namely, those in regard to infectious diseases. The average number of cases of enteric fever over a period of ten years was 535, whereas in 1930 the figure was as high as 766. The average figure for diphtheria over a period of ten years was 8907, whereas the figure for last year was 11,580. He would like to have an explanation of these alarming increases. It had been suggested that the cause might be impure water supply, and he would like to know whether the Department endorsed that view. He reserved his judgment in regard to the change in machinery under the Local Government Act. He was far from being satisfied, notwithstanding what the report of the Department of Health said, that the changes in regard to the poor-law would be permanently beneficial. He was afraid that there had been thrown upon the scrapheap a vast number of experienced men and women who had formerly given their expert services to the administration of the poor-law. He questioned whether, to a large extent, the new machinery was not even now breaking down. The work was being handed over more and more to paid officials. It was very desirable that there should be some inquiry into the working of the new Act, and he hoped that a commission would soon be appointed for that purpose.

BLACK PATCHES.

Mr. R. W. **SMITH** said, on the whole, there was a marked improvement in the vital statistics of Scotland, but there were still one or two black patches which could be removed by administrative methods. One of these was maternal mortality, which was rather distressing, because more care was taken of expectant mothers and of the children than ever before. Yet unfortunately the mortality figures were not falling as they ought to do. The Secretary of State had informed the Committee that new forms of medical record were to be instituted in the case of sick persons and he (Mr. Smith) suggested that they should also be supplied in cases of maternal mortality. The great trouble arose from puerperal sepsis, and it seemed to him that by greater care something could be done to prevent the frequency of such case laid before Parliament on Feb. 17th. The first part of the question does not, therefore, arise; and the answer to the second part is in the negative.

Small-pox in India.

Mr. FREEMAN asked the Secretary for India the number of deaths from small-pox which had occurred each year in Calcutta, Bombay, and Madras respectively since the year 1924.—Mr. WEDGWOOD BENN replied: The following table gives the figures of small-pox deaths for which my hon. friend asks:—

Town or municipality.	1924	1925	1926	1927	1928	1929	1930*
Calcutta	316	3,923	934	2,860	558	393	1,831
Bombay	1,231	565	476	841	595	1,126	1,562
Madras	196	762	60	32	246	503	181

* Provisional figures.

TUESDAY, JUNE 30TH.

Foo-supply at Shieldhall Fever Hospital.

Mr. MCKINLAY asked the Secretary for Scotland, if he was aware that patients from the Partick district of Glasgow, until recently inmates of Shieldhall fever hospital, had complained of the food supplied and that the wards were infested with vermin; and what steps he proposed to take to have the matter rectified.—Mr. WESTWOOD (Under-Secretary for Scotland) replied: I have no knowledge of complaints by patients who have recently been in Shieldhall Infectious Diseases Hospital in regard to the food supplied, which is drawn from the same sources as that supplied to other institutions under the Public Health Department of Glasgow. As regards infestation of the wards with vermin, I am informed that certain portions of the hospital have for some time been invaded by small red ants, which established themselves in the kitchen and along the ducts of certain of the wards. Substantial repairs to the kitchen have resulted in their disappearance from that area, but up till now efforts to eradicate them from the ducts of the wards have not been so successful. It is hoped, however, that further improvement will be effected by measures which are being taken under the direction of a medical officer who has had special experience in connexion with insect pests.

Workmen's Compensation in Mauritius.

Mr. MCSHANE asked the Under-Secretary for the Colonies the reasons why, in Mauritius, the Workmen's Accident Compensation Act, although it had received the Royal Assent, had not yet been put into operation.—Dr. SHIELS replied: The position as regards the Workmen's Compensation Bill in Mauritius is that its consideration was deferred during the final session of the last Council of Government for various local reasons. The Bill was reintroduced at the opening of the new Council in May, and is now awaiting its second reading, the discussion on which was expected to take place to-day.

MEDICAL NEWS

University of Cambridge.

At recent examinations the following candidates were successful:—

THIRD EXAMINATION FOR M.B. & B.CHIR.

Part I., Surgery, Midwifery, and Gynæcology.—R. J. V. Battle, H. E. Blake, E. Bradbury, A. B. Carter, G. T. Cook, A. H. Dunkerley, K. V. Earle, G. R. Ellis, C. D. Evans, C. L. Ferguson, T. C. Gipson, D. R. Goodfellow, H. F. Green, G. W. Hall-Smith, A. S. Herington, J. Howell, J. Hughes, J. T. Irving, N. M. James, L. P. Jameson Evans, R. A. Jones, A. W. Langford, A. Lister, B. F. Longbotham, J. V. Lucas, G. C. Martin, F. C. Mayo, D. A. Metcalf, A. K. Monro, J. G. More Nisbett, G. G. Mowat, R. W. C. Murray, W. H. Mylechreest, C. R. L'E. Orme, J. L. Parker, G. T. Partridge, C. G. Roberts, I. C. Robertson, E. Sharp, N. Stevens, R. A. Sykes, J. E. J. Thomas, G. M. Tickler, A. B. Waters, M. Westwood, C. E. R. Wood, and A. H. Zair.

Part II., Physics, Pathology, and Pharmacology.—C. P. Bailey, G. N. Bailey, J. S. Barker, L. T. Bond, C. C. Bryson, H. S. Buckland, G. F. Carey, A. B. Carter, C. L. Collins, G. T. Cook, J. H. Cyriax, A. Eckford, W. A. Fell, D. R. Goodfellow, F. T. J. Hobday, J. T. Irving, G. D. Kersley, C. R. T. Lane, D. L. Lewis, J. W. S. H. Lindahl, G. G. Ludgater, E. H. W. Lyle, D. B. McGavin, J. M. Matthew, C. W. Morley, W. M. Niblock, R. G. Orr, J. L. Parker, J. Petro, W. H. Poole, H. E. W. Roberton, M. H. Salaman, G. H. Sanderson, W. W. Sargant, P. G. Scott, J. Sowerbutts, J. H. Spence, T. C. Stamp, E. T. W. Starkie, H. C. Stewart, J. W. Summerhayes, A. W. Vaisey, J. G. Vincent Smith, E. D. Ward, G. W. Whittall, L. K. Wills, T. D. G. Wilson, C. H. Wrigley, and R. H. Young.

Hospital of St. John of Jerusalem.

The King has sanctioned the following promotions in and appointments to the Venerable Order of the Hospital of St. John of Jerusalem:—Knight of Justice: Col. Sir James Purves-Stewart. Knight of Grace: Col. the Hon. Murray MacLaren. Commanders: Maj. Sir Thomas Houston, Dr. E. A. Chill, Sir P. Horton-Smith Hartley, Lt.-Col. H. J. Barnes, Dr. R. Clegg, Dr. F. N. Kay Menzies, Surg.-Vice Admiral Sir Arthur Gaskell, and the Hon. J. H. King, M.P. Officers: Lt.-Col. G. E. Peacock, Lt.-Col. G. Mackie, Capt. A. C. W. Knox, Dr. W. E. Thompson, Dr. A. Wilson, and Sir Squire Sprigge. Serving Brothers: Dr. W. Lee, Dr. L. A. Line, Dr. F. S. Booth, Dr. L. Featherstone, Dr. C. A. Verco, Dr. W. G. Shellshear, Dr. W. B. A. Moore, Dr. D. H. Griffiths, Dr. R. L. E. Downer, and Lt.-Col. G. C. E. Simpson. Associate Serving Brothers: Major Sorab Kaikhosru, Engineer, and Dhanjibhai Hormasji Mehta.

International Association for Preventive Pædiatrics.

The first meeting of this association will be held at The Hague on Sept. 7th and 8th, 1931. The subjects for discussion are to be Return Cases of Scarlet Fever and the Mortality in the First Ten Days of Life. Information about the meeting can be obtained from the secretary, Prof. G. Scheltema, 14A, Poelstraat, Groningen, Holland.

Medical Society of Individual Psychology.

A dinner of the Society will be held at the Florence Restaurant, London, W.1, on July 9th, at 7.15 for 7.30 P.M. (morning dress), and will be followed by the General Meeting.

London Jewish Hospital Medical Society.

The annual general meeting of the Society took place on June 25th, the President, Dr. L. Mandel, being in the chair. The following officers were elected for the session 1931–32:—President: Mr. M. Sorsby. Vice-President: Dr. L. Turiansky. Treasurer: Dr. Hannah Billig. Hon. Clinical Secretary: Dr. H. Avery. Hon. General Secretary: Dr. L. Phillips. Committee: Dr. Leah Appell, Dr. Borst, Dr. D. Krestin, Mr. S. I. Levy, Dr. M. Marcus, Dr. Fanny Robinowiz, Dr. M. Tree, Dr. A. D. Woolf. A vote of thanks to the outgoing President was proposed by Dr. Phillips and seconded by Dr. Schwarzman.

John Mallet Purser Lecture.

The first lecture was delivered in the School of Physic, Trinity College, Dublin, on June 26th, by Sir Edward Sharpey-Schafer, F.R.S., on the New Physiology. The chair was taken by Sir Almroth Wright, F.R.S., who had been admitted on the previous day the first Honorary Fellow of Trinity College. The lectureship was founded last year by Miss Jane Purser in memory of her brother, the late John Mallet Purser, who was King's professor of the Institute of Medicine in the School of Physic from 1874 to 1901, and Regius Professor of Physic in the University of Dublin from 1917 to 1925. Sir Almroth Wright had been one of his pupils. As King's professor Purser was the first teacher in Ireland to give systematic instruction in physiology and pathology.

Springfield Nurses' Home.

Last week Princess Mary opened the new nurses' home at Springfield Mental Hospital, Upper Tooting. The hospital now accommodates 1400 patients, and the new home is designed to house 140 nurses. The Princess also opened the new premises of the Wandsworth and Tooting Children's Clinic at Lower Tooting.

St. Thomas's Hospital Out of Debt.

For the first time since the war St. Thomas's Hospital is free of debt owing to donations of £104,000 from Sir William Morris and £100,000 from Lady Houston. As a mark of appreciation the portraits of these two donors have been hung in the hospital.

General Lying-in Hospital.

The annual report shows that in 1930 this institution in York-road, Lambeth, received 1068 in-patients, an increase of 53, and that 1165 women were attended and delivered at home, an increase of 65. There was one maternal death, for which the post-mortem failed to show any cause.

OBITUARY

DUDLEY WILMOT BUXTON, M.D., B.S.Lond., M.R.C.P.Lond.,

CONSULTING ANÆSTHETIST, UNIVERSITY COLLEGE HOSPITAL.

We regret to announce the death of Dr. Dudley Buxton, the well-known authority on anæsthetics, which occurred on Sunday last, June 28th, in a nursing home on his seventy-sixth birthday.

DR. DUDLEY BUXTON.

Dudley Wilmot Buxton was born in 1855, the son of Mr. Harry Wilmot Buxton, a barrister-at-law of the Middle Temple. He received his general education at private schools, and University College, London, and his medical training at University College Hospital. He entered the hospital in 1878 and was a successful student, qualifying as M.R.C.S. three years later and taking the M.B. and B.S. London in 1882 with honours in each instance. He served as house physician and house surgeon at his hospital and proceeded to the M.D. degree in 1883 and took the M.R.C.P.Lond. in the following year. Before deciding on the career of a specialist he leant towards general medicine and was appointed by Sydney Ringer, then Professor of Medicine in the College, to be his assistant. Ringer stimulated him to study the scientific aspect of medicine, and helped him in his early work, undertaking with him an inquiry into the effects of acids, alkalies, and cocaine on the heart. At this time Buxton edited the fourth edition of Waring's Therapeutics, and was elected physician to the Marylebone General Dispensary.

But in 1885 he decided to specialise in anæsthetics, a subject which 45 years ago was in its youth as an exact science. He obtained the post of anæsthetist at University College Hospital, giving his services also to the Hospital for Women in Soho-square, to the Royal Dental Hospital, and in particular to the National Hospital, Queen-square. With his marked attainments and with these large opportunities for their exhibition, he soon became recognised as a leading exponent of his branch of medicine. As a lecturer he was an indefatigable instructor, triumphing over difficulties of elocution, and his pupils at University College Hospital and the Royal Dental Hospital were equipped in a way that was quite unusual in British medical schools to undertake the responsiblity of administering anæsthetics when they entered upon practice. His ability in teaching his subject was recognised by those who came back to learn from him many years after qualification—in fact, his recognition of the importance of every doctor going into practice with a competent knowledge of anæsthetics affected the teaching of this subject throughout all the country. He wrote largely and instructively in numerous journals, publishing researches into the action of various anæsthetics, and one work of his on the uses and administration of the different agents passed through six editions. On nitrous oxide, ether, and chloroform alike his observations were valuable. At first they were founded on the physiological deductions from experimental work, but later on an enormous and delicate experience, when he was often aided by the scientific discrimination of his great friend Sir Victor Horsley. It is due to Buxton's work on nitrous oxide that continuous nitrous oxide gas is now administered. With regard to ether he felt that the gas-ether induction was a kinder method than the open ether induction, while his study of colonic ether interested him greatly from the outset; he held that there should be further investigation of this method, and consequently the recent introduction of avertin as an anæsthetic was of great interest to him.

Buxton, both from his range of knowledge and his practical opportunities, was an acceptable figure on any committee of inquiry into anæsthetics. He served as secretary of a Special Chloroform Committee appointed by the British Medical Association, was a member of the Departmental Inquiry into the giving of anæsthetics, and made a valuable contribution to our knowledge of chloroform in his addendum to the Hyderabad Commission on Chloroform. At this time Buxton was the advisor of THE LANCET upon the subject of anæsthetics; and his labours in connexion with the Hyderabad Commission, undertaken for us, were of a difficult character. In 1888 the Nizam of Hyderabad, at the instance of his residency surgeon, Surg.-Major E. Lawrie, instituted an inquiry into the action and effects of chloroform, Lawrie desiring to prove that the risks attached to its use were preventing the anæsthetic from being sufficiently or properly used. The report of the Nizam's committee of inquiry was forwarded to THE LANCET, when various comments upon the conclusions were made. As a result, THE LANCET was invited to send a representative to hold a further inquiry on the spot. Lauder Brunton was selected for the task and a second inquiry of an elaborate sort was undertaken under his direction, the expenses being defrayed by the Nizam. The results of that inquiry were published as a supplement to THE LANCET in 1893 under the editorship of Dr. Dudley Buxton, who summarised, with extreme care and ability, the voluminous records, and furnished a clinical addendum. During later years he wrote monographs for the *British Journal of Anæsthesia* on Clover, Snow, Lister, and others who had influenced the development of anæsthesia. Such articles as Anæsthesia: its Physical and Psychological Aspects, and Sleep and Her Twin Sister Death, are typical examples of his broad views. His well-known work "Anæsthetics," reached its sixth edition in 1920, by which time its size had been more than doubled in accord with the developments of exact knowledge. His position as one who had contributed notably to these developments is shown by the posts which he filled, for he was at one time President of the Society of Anæsthetists, at another, of the Section of Anæsthetics of the British Medical Association, while he was selected to be President of the Section of Anæsthetics at the International Medical Congress, held in London in 1913.

During the war Dudley Buxton was anæsthetist to King George V. Hospital, in addition to his other appointments, and shortly after the termination of the world struggle he retired from London, having felt the stress of his long and arduous professional life. For 40 years he had had a cottage in Hertfordshire, and later he built a house near Boxmoor to which he retired in 1919. He was made consulting anæsthetist to the three great institutions with which he had been connected, University College Hospital, the Royal Dental Hospital, and the National Hospital, Queen-square, while residence so near London enabled him to keep green his many friendships. He soon found the interest of the countryside and of gardening insufficient for him, and took his recreation in administering anæsthetics and teaching the nurses at the West Herts Hospital until impaired health prevented these activities. He thus may be said to have died in office. To the regrets of his personal friends will be added those of the very many professional colleagues who recognised in Buxton a pioneer as well as an enthusiastic worker in his important field of medicine.

In 1884 he married Louise, daughter of the Rev. Thomas Grey Clarke, by whom he had three sons; the eldest, Leonard, formerly a Beit scholar, is now lecturer in physical anthropology at the University of Oxford; the second son, St. John, is surgeon to King's College Hospital; and the third Leycester, is dental surgeon to University College Hospital

WILLIAM DARLING, M.B., F.R.C.S.Edin.

Dr. William Darling, who died on June 23rd at the age of 60, was a well-known Edinburgh practitioner, who came of a family of school teachers and was himself a trained and acting teacher before entering medicine. He graduated M.B., Ch.B., at Edinburgh in 1899, he held hospital appointments in Leith, Manchester, and London, and studied for a year at Marburg, obtaining later special qualifications in surgery and public health. His educational training brought him into contact with training college work and when courses in personal hygiene were first established at these colleges Dr. Darling was selected as lecturer. For 20 years or so students and school children passed under his medical scrutiny. He always took a keen interest in the work of the R.A.M.C., and had served in South Africa. On the outbreak of war in 1914 he was called up as a member of the special reserve and took part in the retreat from Le Cateau and Mons. He was in the first battle of the Marne, and later on the Aisne; he was twice mentioned in dispatches and was awarded the Military Cross for services on the Somme. He was finally gazetted out as Lieutenant-Colonel in the R.A.F. Medical Service, to conduct a large general practice until within a few weeks of his death. A colleague writes: "Dr. Darling had a multitude of friends both among the general public and the profession. As an inspiring officer he will be very badly missed; for he had given a lifetime to the training of young officers and to promoting the work in the special reserve. He many times assured me that he would not for the world be without the experience of the Mons retreat."

THE LATE BARON KITASATO.

LAST week we published a biographical notice of Prof. Shibasaburo Kitasato with an appreciation by his friend and pupil Prof. Mikinosuke Miyajima. We are indebted to Prof. W. Bulloch for some further details of the six years spent in Robert Koch's Institute. It was in 1885, Prof. Bulloch writes, that Kitasato was sent to Europe by the Japanese Government to study bacteriology and infectious diseases, and he settled in Berlin at the Hygienisches Institut under Robert Koch, who was then nearing the height of his fame. Koch had recently (1882) discovered the causes of tuberculosis and (1883) of cholera; and his Institute was a mecca to which students were flocking from all parts of the world. Kitasato stayed in Koch's Institute for six years (1885–1891), and was given the honorary title of Professor of the University of Berlin. He worked in a small room, and was always busy. He soon mastered the rigorous bacteriological technique imposed by Koch on his pupils, and about 1887 began to publish researches on cholera and typhoid bacilli and on anthrax. He discovered several new organisms, one with a remarkable musk odour, *Fusisporium moschatum*. In 1889 he cultivated in a pure state *Bacillus tetani*. He showed that it was an obligate anaerobe, and by the accurate study of its distribution in the body was led to infer—and he was the first to do so—that lockjaw is essentially an intoxication disease. The actual toxin of tetanus was discovered by Knud Faber, 1890. In that year Behring and Kitasato discovered tetanus antitoxin and laid the first foundations of serum therapy. The brief but classical research of Behring and Kitasato was published in the *Deutsche Medizinische Wochenschrift* of 4th December, 1890, and contained the main facts regarding tetanus antitoxin—its properties, its durability, its passive transference, and its specificity.

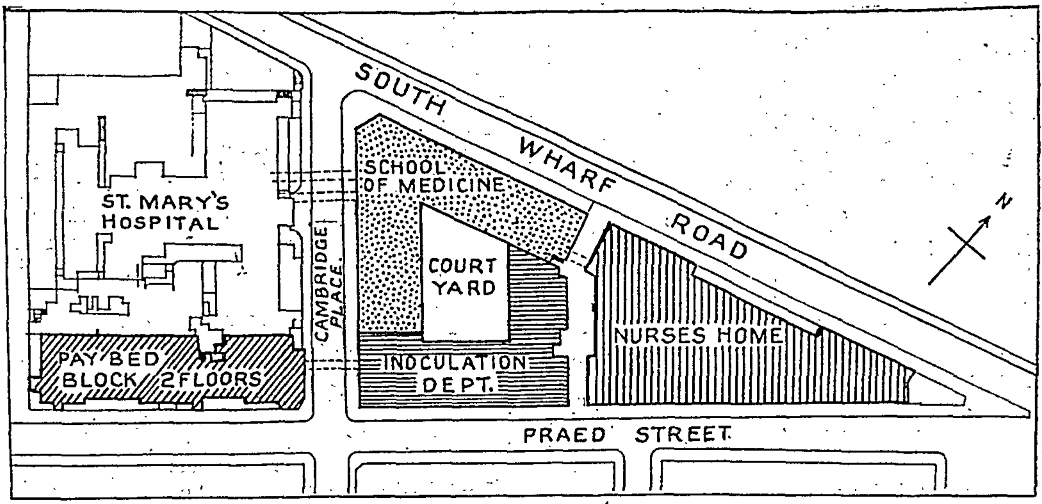
After his return to Japan in 1891, Kitasato founded the private bacteriological institute at Shirokane, across the bay from Tokyo city, which was first subsidised by and then taken over as a Government department under the name Imperial Japanese Institute for Infectious Diseases. Here, writes Prof. Bulloch, he created quite a Japanese School of Bacteriologists, amongst whom may be specially mentioned Kioshyi Shiga and S. Hata. In 1894, Kitasato was sent by his Government to Hong-Kong to investigate the nature of plague, which was occurring in epidemic form. This expedition resulted in his greatest discovery, *Bacillus pestis*. His work was done in record time. With Aoyama, the morbid anatomist, Kitasato landed at Hong-Kong on June 12th, 1894, and began his study on June 14th. In an autopsy he found numerous bacilli in the buboes and in the heart blood. He inoculated mice from the splenic blood, and on the same day also obtained blood from a living case of plague. Cultures were made, and all grew. They were inoculated into mice, guinea-pigs, rabbits, and pigeons. All died except the pigeons. He found the bacilli in fifteen cases of plague, and got out all the main facts of the bacteriology of bubonic plague. His first publication in English on plague appeared in the columns of THE LANCET (1894, ii., 428–430), and was a very complete piece of work.

A WAR MEMORIAL HOSPITAL.—Lady Violet Astor recently opened the Edenbridge and District War Memorial Hospital which takes the place of a house temporarily adapted in memory of men from the district who fell in the war. The building and equipment have cost £18,000. At the opening ceremony Mr. W. E. Tanner, the hon. consulting surgeon, said that the hospital was not surpassed in any part of the world, and that it was proposed to treat any kind of illness with the exception of infectious disease.

ST. MARY'S HOSPITAL, PADDINGTON.

FOUNDATION-STONE CEREMONY.

THE foundation-stones of the medical school and pathological institute of this hospital were laid on June 30th by H.R.H. the Duchess of York. The new buildings will occupy the island site between Praed-street, Cambridge-place, and South Wharf-road. The medical school will be in the north-west corner with administrative offices, common room, speech hall, and library on the ground floor; garage, cloak-room, billiard-room, swimming bath, and dining-room in the basement; and laboratories and classrooms above. The pathological institute will include laboratories, workrooms, animal rooms, and out-patients' department, and will be connected with the hospital by a bridge over Cambridge-place. The eastern angle of the site is reserved for a nurses' home.



Plan of the new building.

Lieut.-Colonel H. E. Verey (chairman of the hospital) welcomed the Duchess of York, and said that this was a great day for the hospital. The new premises would allow the provision of 30 more maternity beds in the old inoculation department, and he hoped it would not be long before the new nurses' home could be erected, making room for more maternity beds and for pay-beds. When the scheme was completed, the buildings would not fear comparison with those of any hospital in London. Nevertheless, it was not buildings that made a city but the spirit of the men that dwelt in it. The hospital had had a distinguished line of royal Presidents but had never been happier than in its present President, the Duchess of York.

Mr. Stanley Baldwin pointed out that less than a quarter of a century ago medical schools had been dependent on students' fees for their very existence. Now there were grants, but all capital expenditure, for buildings and research, still came from the public. This important fact was often forgotten by those who gave generously to hospitals. With the medical schools rested the training of future medical men, but nothing was done to help them to discharge that great obligation. As an example, he took the subject of maternal mortality, and the need for obstetric beds, training, and research. Extra maternity facilities should essentially be provided in hospitals with medical schools. The money available for the buildings being erected at St. Mary's had been principally the *gift of a few individuals* endowed with vision: Lord Revelstoke, Lord Iveagh, Lord Beaverbrook, and others, who were seeking the right way in which the heart and the head could combine in making a return for the generosity shown to them by life. The need must be brought to the notice of the general public. There was no field more fertile for human health and human happiness. Mr. Baldwin spoke warmly of the work of Sir Almroth Wright—a man in the true tradition of Jenner—and said that our country, which contained more latent talent than any other country in the world, might contain many potential Almroth Wrights. To find and endow this hidden talent was the great need, and this called for the endowment of scholarships. He prayed that the very rich might learn the superlative joy of giving, and that a due proportion of the exceptional men in the country, whatever their rank, might be led to join the great healing profession.

Dr. C. M. Wilson proposed, and Sir Almroth Wright seconded, a vote of thanks to Her Royal Highness. Dr. Wilson urged students to acquire a reverence for facts and a passion for exactitude, saying that these were the essential elements of Lord Revelstoke's mind. Research students must look on old problems from new angles, and see the world with the eager eyes of a child. Conventional thought, useful enough in its way, was a grave handicap in research. Medical education was the key to the health of the nation.

Sir Almroth Wright said that they were all out for this business of doing good; the question of reward fell right out of consideration. There was no reward for seeing or hearing or doing good. If the eye did not get pleasure from seeing or the limbs from moving, no amount of thanks would help them. Doing good was part of the vital energy of man that needed outlet. He especially mentioned his colleagues in the laboratories, Sir Max Bonn, Lord Iveagh, and Sir Edwin Cooper, the architect, who had designed an attractive home for their work.

The Duchess of York then laid the two foundation-stones with a mallet used by Queen Victoria, King Edward VII., and King George V. The Bishop of Kensington offered prayers of dedication.

The funds for the commencement of the new buildings have been derived from gifts of £63,000, £25,000, and £40,000 from Lord Beaverbrook, the estate of the late Lord Revelstoke, and the Earl of Iveagh respectively. The committee of the inoculation department has contributed £20,000, and other gifts total £10,000. To complete the programme a further sum of £350,000 is needed, and for this a public appeal is being made.

A STATISTICAL SURVEY OF SIERRA LEONE.

THE difficulties attending the composition of vital statistics in most of our tropical dependencies are almost insuperable. The desirability of such reliable statistics is acknowledged on all hands, and were it possible to obtain records in any way comparable with those compiled in the older civilised countries, it would aid the cause of development and ease the burden of administration. That more strenuous efforts should be made to supervise the public health figures in our African colonies has recently been urged by public health authorities, notably by Major Granville Edge.[1] But the obstacles are great; except in the larger centres of administration, neither the medical organisation nor the personnel is in existence, and furthermore native superstitions and customs discourage too intimate inquiry into their home affairs. Post-mortem examinations cannot be performed as a routine in native bush villages, even where prejudice does not forbid the practice altogether. Prof. D. B. Blacklock has tried to overcome some of these difficulties by a sampling survey of a selected population in Sierra Leone.[2] From November, 1927, the survey was continued, with interruptions, till October, 1929. A period of four and a half months was allocated to the Northern and a year to the Central and Southern Provinces.

The Northern Province.

In the Northern Province four journeys were undertaken, being the principal villages visited. The total number of persons examined was 4337—the majority being subjected to a complete, the remainder to a partial examination. In his report of the results obtained the diseases are arranged in alphabetical order. Some of them are of special interest in view of popular impressions on native immunity from certain diseases. Numerous cases of arthritis were encountered, 143 showing deformity and swelling of joints. Blood examination of 636 persons showed the percentage infected with malaria parasites to be very high—57 per cent. Films of blood taken at night revealed *Microfilaria bancrofti* in 15 per cent., and the day blood of 257 persons revealed *Microfilaria loa* in less than 1 per cent. *Microfilaria perstans* was demonstrated twice.

THE PREVALENCE OF SKIN DISEASES.

Skin diseases were widespread. Apart from the cutaneous lesions of leprosy and yaws, scabies, impetigo, and pyosis were common. Pellagra-like eruptions were present on the hands and feet. In view of recent findings in Central Africa it is satisfactory that no cases of lung disease due to the tubercle bacillus were noted. Several patients, however, showed suspicious emaciation and physical signs. Human trypanosomiases contributed very little to the catalogue of the diseases found in areas visited during this survey. No cases actually suffering from small-pox were encountered, though 261 who gave a history of previous small-pox had not been vaccinated, great dread being evinced of this trivial operation. Gangosa, or the repulsive mutilating rhinopharyngitis, appears to be common; no less than 64 cases were seen. It was noted too in four subjects under 10 years of age. Evidence was forthcoming that gangosa is an expression of a generalised disease. No less than 87 per cent. of those afflicted with gangosa gave a history of yaws, and thickenings of the large bones were frequently observed. Gonorrhœa appears to be alarmingly prevalent, the youngest sufferer from urethritis being a child in arms. Of a total of 732 males over 14 years of age, evidence of existing gonorrhœa was found in 304. Perineal fistula and scrotal sinuses were definitely associated with an active infection. No less than 408 persons were found affected with hernia or hydrocele, umbilical hernia being more than twice as common as all the other forms of hernia combined. It is much more frequent up to 10 years of age. The section on tumours is disappointing. Lipomata are said to be relatively common in natives of this part of the Protectorate, but though the presence of other tumours including one definite case of scirrhous carcinoma of the breast is noted, no indication is given of the incidence of simple or malignant tumours in the population surveyed. Yaws was very prevalent; the number of cases from the Bullom region far exceeded the number of cases of this disease seen in other areas visited. No person of over 50 years of age was found affected, but the proportion of young people under 10 years of age with yaws was overwhelming. In 26 per cent. the primary lesion occurred on the upper extremity; in 54 per cent. on the lower extremity; and in 7 per cent. on the head and neck. The people themselves welcome the treatment of yaws by injections, and according to Prof. Blacklock there is some evidence that its permanent cure of yaws can be brought about by a few injections of bismuth or arsenic.

The Southern Province.

The second part of his report concerns itself with the Central and Southern Provinces. The same routine was observed over one year, and the number of persons examined was greater, being 5153, of whom 3678 were males and 1475 females. The blood of 151 persons was examined for microfilaria and trypanosomes. In five, *Microfilaria bancrofti* were found, and in one specimen of blood, trypanosomes were present. Satisfactory evidence of the existence of typhoid and paratyphoid infections was obtained. Out of a total of 556 persons whose serum was examined, the number of positive reactions ws 61—namely, 28 with *B. typhosus*, 3 with *B. paratyphosus* A, and 30 with *B. paratyphosus* B. There appears to be little doubt that the typhoid group occurs sporadically in Sierra Leone, and that the illness which affected a number of girls in the Moyamba American Mission School in 1926 was of this nature. Elephantiasis appears to be as commonly distributed as in the Northern Provinces, 42 cases being noted. Disfiguring gangosa was not so widespread as in the Northern Provinces, but gonorrhœa appears to be even more prevalent than in the north, the incidence amongst the population being about 14 per cent. It is suggested that schools could do a great deal of valuable work in ascertaining more details about the distribution of physopsis. Schools should be provided with samples of snails and a record could be kept by the headmaster of such streams and swamps in which these snails were found by the children. Gonorrhœa is so prevalent and primary syphilis so rare in this community that it is concluded that some factor is at work which either does not permit *S. pallidum* to cause infection or prevents syphilitic sores of the genitals from assuming a characteristic form. Lesions affecting the soles of the feet were found, due to the aftermath of a previous yaws epidemic, while no less than 297 cases of fluid eruption of secondary yaws were seen.

---

[2] Report on a Survey of Human Diseases in the Protectorate of Sierra Leone. By D. B. Blacklock, M.D., Professor of Tropical Diseases of Africa, University of Liverpool; Director of the Sir Alfred Lewis Jones Laboratory, Freetown. Freetown: Government Printer.

General Observations.

This important work ends with a survey of general questions. An opportunity arose of making a re-survey of the village of Kaiyima, where extensive sanitary reforms had been undertaken as the outcome of a previous report in 1923–1924. It is satisfactory to note that the sanitary improvement carried out at Kaiyima, combined with the activities of the medical officer, have caused a diminution in the goitre percentage from 41 to 23 in males, and from 72 to 52 in females. A diminution in the schistosomiasis evidence could also be recorded, giving a positive percentage of 42 as compared with a percentage of 65 in 1923. A well-deserved tribute is paid to the Paramount Chief who, alone of all the Chiefs, has fulfilled his promise of trying to make his town healthy. In the survey of the Central and Southern Provinces, it was observed that far more persons of advanced age were seen at examination, and that large numbers of persons with congenital and other abnormalities appeared to survive. In every village there were found people who understood English and were familiar with several European drugs. Their superior economic status and their better and more varied dietary presumably increases their resistance to disease, for generally speaking the disease incidence was less than in the Northern Province. In conclusion it is strongly advocated that aspirants to the posts of Paramount Chief, Chief, and Sub Chief, should be required to show some knowledge of, or evince some interest in, the measures by which the health of their people could be improved.

PUBLIC HEALTH SERVICES

MENTAL HOSPITAL REPORTS.

The Leicester City Mental Hospital at West Humberstone had 976 patients in residence on March 31st last, and the accommodation for recent and acute cases has now become inadequate. A new nurses' home is being built and the committee are considering the provision of a reception hospital. The recovery-rate for the year was 39·26 per cent. and the death-rate 7·15 per cent. This is a slight decline in the former and increase in the latter, both accounted for by the admission of chronic and unsatisfactory cases from the North Evington Infirmary. The cause of death was verified in 86 per cent. of cases by post-mortem examination. There was a mild outbreak of dysentery among the women in October, but no deaths resulted, and otherwise the general health was good. Parole is allowed to 60 per cent. of the men and 38 per cent. of the women, and during the year leave of absence was granted to men on 3576 occasions and to women on 1474 occasions, while 77 per cent. of the patients were usefully employed. General paralysis is treated by malaria; during the year 15 patients were inoculated, of whom five died and four have been discharged. Since the treatment was first introduced in 1924, 81 patients have been treated, with a discharge-rate of 24·7 per cent. and an improvement-rate of 18·5 per cent. In addition to the work with malaria and with the dysentery outbreak, the pathological laboratory carried out a large number of routine observations and investigated the Vernes test. The visiting dentist performed 351 operations, and inspected 40 patients, whose teeth were in good condition. The arrears of dental disease before a dental clinic was held have now been overtaken and no patient's health or happiness is burdened any longer by a septic mouth. Of the 114 male and female nurses, 24 men and 25 women are certificated or registered; five members of the staff obtained their certificate during 1930. An out-patient clinic is held weekly, and the committee are considering the appointment of an after-care officer.

The Leicestershire and Rutland Mental Hospital at Narborough had 747 patients on its register at the end of last year. The recovery-rate was 34·6 per cent. and the majority of those recovered were first sent out on trial. The death-rate was 8·2 per cent. and the cause of death was verified by examination in 86·4 per cent. of cases. The general health was good during the year and there was no epidemic disease. The institution, like so many others, is overcrowded, and the committee is taking steps to provide accommodation for quiet senile cases in a "poor-law" institution. Unfortunately, mental defectives are still housed in this mental hospital, and the proposed colony will not be available for them for some time. Great improvement has been brought about by the provision of a bread-slicing machine and a butter-pat-making machine; instead of the thick slabs of bread spread with margarine hours before it was eaten, each patient now receives two slices of nicely cut bread and two pats of margarine (10 per cent. butter), kept in the cold room until a few minutes before the meal. Not only do the patients greatly appreciate this, but at least two hours of a nurse's time is saved in each ward, and the new system ensures that every patient gets a correct ration of fat. The uniform of the staff has been changed to a modern type, which greatly pleases the wearers and helps to increase the "nursing" atmosphere. The laboratory started to function at the close of the year, and clinical rooms have been provided. Cases of general paralysis—of which only three were under treatment this year—have been treated by sulpharsenol, but malaria inoculation will be used in future. A dental surgeon has been appointed, and members of the staff of the Leicester Royal Infirmary act as consultants when required. A cinematograph machine was provided during the summer, to the great delight of the patients. The use of parole has been extended.

The Cumberland and Westmorland Mental Hospital had 854 patients resident on Dec. 31st last. The recovery-rate was 43 per cent.—58 per cent. for the males—and the medical superintendent attributes this gratifying figure largely to judicious granting of parole and trial visits. The death-rate has dropped from 8·4 to 6·2 per cent. and the phthisis rate has also fallen. There was one case of paratyphoid fever, but otherwise the health of the community was good. The medical superintendent pleads for the provision of an admission block arranged on modern lines and for the appointment of a social worker. He is also anxious to introduce an occupation centre. A laboratory is being established. The staff are prepared for the R.M.P.A. examinations.

There were 1082 patients in the County and City of Worcester Mental Hospital at Powick at the end of last year. A day room and a dormitory have been redecorated and set apart for recent admissions, and a verandah is to be added to this department. The recovery-rate for the year was 31 per cent. and the death-rate 6·2 per cent. Autopsies were held in 75·8 per cent. of cases. The general health was good, except for one case of typhoid and one case of paratyphoid fever. The dentist visits once a fortnight. Electric light is to be installed shortly and it is hoped that a cinema, X ray and ultra-violet ray plant will soon follow. During the year five male and five female nurses obtained their R.M.P.A. certificates.

The Glamorgan County Mental Hospital at Bridgend was overcrowded at the end of last year by no less than 295 patients, the total in residence being 2108 on Dec. 31st. The recovery-rate for the year was 29·7 per cent. and the death-rate 6·6 per cent. Post-mortem examinations were performed on 52·5 per cent. of cases. The general health was remarkably good considering the overcrowding, and the only epidemic disease, apart from influenza, was chicken-pox (four cases) and erysipelas (one case). The dental surgeon visited fortnightly and attended 258 patients. The visiting surgeon performed three operations, and 60 diagnostic X ray photographs were taken. Over 60 patients were allowed out on trial before discharge, but only seven of them received money allowances. The visiting commissioners deplore the absence of a laboratory, continuous bath, malarial treatment for general paralysis, and adequate verandah accommodation. Parole is allowed to 20 men beyond the estate and to 125 within it. Seven women nurses are employed on the male side and 112 men and 44 women are certificated or registered. Fifteen attendants and eight nurses obtained their R.M.P.A. certificate last year.

MENTAL DEFICIENCY.

The Royal Eastern Counties' Institution for the Mentally Defective at Colchester has now over 1400 patients on its books. Many improvements were carried out during last year, at a cost of nearly £7000. A new single-storey hospital has been built, with 31 beds. This left accommodation on one side of the old hospital for the senior male patients, who needed a quiet place where they could do as they liked; the oldest "boy" is 84 and the next is 77. The furniture for both these new departments was made by inmates, who also built two staff cottages, doing all the work except the internal plastering. Central heating has been installed at Bridge Home, where it was a necessity for the low-grade boys with poor circulations. A wireless installation has been bought and so also has an electric gramophone, which will broadcast to all stations in the institution. A great many other minor improvements have been made, the greater part of the work being done by the boys and girls themselves. During the year 58 patients were sent out on licence, bringing the total on licence to 115. Thirty (20 per cent.) returned during the year; 12 of these, however, only returned for holidays or illness and went out again. Only two definitely came back for bad behaviour. There were only 17 deaths during the year, which is very satisfactory when it is remembered that many of the children are physically disabled and of so low grade that they seldom seem to know when they are ill, and only the most careful observation on the part of the staff detects the first beginnings of ill-health. The guides and brownies have now taken 420 second-class and proficiency badges and the scout troop and cubs have had a successful year, having won over a hundred second-class and proficiency badges. There has been a steady decline in the number of deaths from tuberculosis; this seems to date from 1905, when the ventilation of the institution was remodelled. There has now been no case of diphtheria since 1925 when the Schick test was instituted as a routine. Dr. F. Douglas Turner discusses the causation of mental defects and derives hope from the general tendency at the present time to ascribe at least half the cases to disease, toxæmia, or injury. He welcomes the appointment of a research medical officer and a social investigator who are to make the fullest possible investigation into each patient and carry out such lines of research as occur to them. Discussing the duties of local authorities under the Local Government Act, he stresses the importance of providing one all-embracing colony for every type of defective; the different types will live in different classes according to age, conduct, and mental capacity, but the colony must include all those for whom the local authority is responsible, except the dangerous cases.

Medical Diary

SOCIETIES.

OXFORD OPHTHALMOLOGICAL CONGRESS.

Thursday, July 9th.—10 A.M., in the Department of Human Anatomy, Opening Address by Mr. A. B. Cridland. Symposium on the Diagnosis of Intracranial New Growths, by Mr. Leslie Paton, Sir Percy Sargent, Dr. H. M. Traquair, Mr. Norman Dott, and Prof A. Schüller.

Friday.—11 A.M., Doyne Memorial Lecture by Mr. P. H. Adams.

ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION: Annual Meeting at the Royal College of Physicians, Dublin.

Wednesday, July 8th.—2 P.M., Presidential address by Mr. R. R. Leeper on the Progress of Psychiatry.

Thursday and Friday.—10 A.M., Papers and discussions.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

Monday, July 6th, to Saturday, July 11th.—St. Peter's Hospital, Henrietta-street, W.C. Wed., at 5 P.M. Demonstration of cases in the Out-patient Department and Urethroscopies by Mr. A. H. Harkness. Open to men only, free.—Hospital for Diseases of the Skin, 71, Blackfriars-road, S.E.: Fri., at 6 P.M., Demonstration of Cases by Dr. W. B. Winton. No fee.—Royal Waterloo Hospital, Waterloo-road, S.E. Wed., 4.30 P.M., lecture by Dr. G. M. Slot on Recent Advances in Treatment of Gastro-Intestinal Disease.—St. John's Hospital, Lewisham. A special course in Diseases of Children by Dr. John Gibbens. Every afternoon, and Sat. morning.—Prince of Wales's Hospital, Tottenham, N.15. Intensive course in medicine, surgery, and the specialties, for two weeks, 10.30 A.M. to 5.30 P.M. (first of two weeks).

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.

Monday, July 6th.—10 A.M., Gynæcological Ward Visit. Genito-Urinary Operations, Skin Department. 11 A.M., Surgical Ward Visit. 2 P.M., Surgical Ward Visit. Medical, Surgical, Eye, Gynæcological Out-patients.

Tuesday.—9.30 A.M., Operations. 10 A.M., Medical Ward Visit, Dental Department. 11 A.M., Throat Operations 11.30 A.M., Surgical Clinical Demonstrations. 2 P.M., Medical, Surgical, Throat, Out-patients, Operations, Medical Ward Visit.

Wednesday.—10 A.M., Medical Ward Visit, Children's Medical Out-patients. 2 P.M., Medical, Surgical, and Eye Out-patients, Gynæcological Operations. 4.45 P.M., Venereal Diseases.

Thursday.—10 A.M., Neurological Department. 11.30 A.M., Treatment of Fractures. 2 P.M., Medical, Surgical, and Eye Out-patients. Genito-Urinary Department Operations.

Friday.—10 A.M., Medical Ward Visit, Skin and Dental Departments. 12 noon, Medical Lecture. 2 P.M., Medical, Surgical, and Throat Out-patients. Operations.

Saturday.—9 A.M., Throat Operations. 10 A.M., Medical Ward Visit, Surgical and Children's Medical Out-patients.

CHARING CROSS HOSPITAL MEDICAL SCHOOL POST-GRADUATE COURSE.

Sunday, July 5th.—10.45 A.M., Mr. L. R. Broster: Surgical Emergencies. 11.45 A.M., Dr. J. E. M. Wigley: Demonstration of Cases of Skin Disease.

ROYAL NORTHERN HOSPITAL, Holloway-road, N.

Tuesday, July 7th.—3.15 P.M. (at the Royal Chest Hospital), Dr. J. Maxwell: Intrathoracic Lipiodol.

ST. MARK'S HOSPITAL, City-road, E.C.

Thursday, July 9th.—4.30 P.M., Mr. Lockhart-Mummery: Perineal Excision of the Rectum, with cinematograph demonstration.

UNIVERSITY OF BIRMINGHAM.

Tuesday, July 7th.—3.30 P.M. (at the General Hospital), Mr. Musgrave Woodman: Infection of the Ear in General Practice.

Friday (at the Queen's Hospital).—3.30 P.M., Mr. J. N. Sankey: The Diagnosis and Treatment of Infections of the Hand.

Appointments

REGAN, D., M.B., Ch.B., N.U.I., has been appointed Asst. Medical Officer and Asst. Schools Medical Officer, Ilford.

RYMER, N. A., M.B., Ch.B., Leeds. Certifying Surgeon under the Factory and Workshops Acts for Hull.

Vacancies

For further information refer to the advertisement columns.

Accrington, Victoria Hospital.—H.S. £150.
All Saints' Hospital for Genito-Urinary Diseases, 91, Finchley-road, N.W.—H.S. At rate of £150.
Association of Surgeons, Wimpole-street, W.—Surgical Scholarship. £350.
Barnsley, Beckett Hospital and Dispensary.—Cas. O. and H.P. £250 and £200 respectively.
Bath, Royal Mineral Water Hospital.—Hon. Electrologist.
Bath and Wessex Children's Orthopædic Hospital, Coombe Park.—H.S. At rate of £120.
Birkenhead General Hospital.—Hon. Surgeon to Ear, Nose, and Throat Dept.
Birmingham, Midland Hospital, Easy-row.—H.S. £150.
Birmingham, Selly Oak Hospital.—Casualty O. At rate of £200.
Bolton Infirmary and Dispensary.—Two H.S.'s. Each £150.
Brighton Borough Infectious Disease Hospital, &c.—Res. M.O. £400.
Bristol Eye Hospital.—Asst. Res. H.S. £100.
Bristol Royal Infirmary—Sen. Res. M.O. £200. Also Res. Dental H.S. and Res. Cas. H.S. Each £80. Also Res. H.P.'s and H.S.'s. All at rate of £60. Also Hon. Asst. to Obstetric Dept.
Bury Infirmary, Lancashire.—Third H.S. At rate of £150.
Cambridge, Addenbrooke's Hospital.—Res. Anæsthetist and Emergency O. At rate of £130.
Cardiff Royal Infirmary.—H.P.'s and H.S.'s to Special Depts. All at rate of £50.
Carnarvon, County of.—Asst. School M.O. £600.
Central London Ophthalmic Hospital, Judd-street.—Out-patient Officer. £200.
Dudley Guest Hospital.—Two H.S.'s. Each £160–£170.
Durham County Hospital.—Two H.S.'s. Each £150.
East London Hospital for Children and Dispensary for Women, Shadwell, E.—Surgeon for Nose, Throat, and Ear Dept.
Enfield Education Committee.—School Dental Surgeon. £500.
Evelina Hospital for Children, Southwark, S.E.—Cas. and Out-patient Officer. At rate of £120.
Exeter, Royal Devon and Exeter Hospital.—H.P. Also H.S. to Spec. Depts. Each at rate of £150.
Fulham Metropolitan Borough, S.W.—Part-time Asst. M.O. for Maternity and Child Welfare Dept. At rate of £300.
Great Yarmouth General Hospital.—H.S. £140.
Guildford, Royal Surrey County Hospital.—H.S. £150.
Hampstead General and North-West London Hospital, Haverstock-hill, N.W.—Cas. Surg. O. for Out-patient Dept. At rate of £100. Also H.P. At rate of £100.
Harrogate Infirmary.—Sen. and Jun. H.S.'s. At rate of £150 and £125 respectively. Also H.P. At rate of £150.
Hospital for Consumption and Diseases of the Chest, Brompton, S.W.—H.P. At rate of £50.
Hove Hospital, Sackville-road.—Res. M.O. £200.
Hove, Lady Chichester Hospital.—Jun. H.P. At rate of £50.
Hull Royal Infirmary.—3rd H.S. At rate of £150.
Ipswich, East Suffolk and Ipswich Hospital.—Cas. O. £120.
Kidderminster and District General Hospital.—H.S. £150.
King's Lynn, West Norfolk and King's Lynn General Hospital.—H.P. At rate of £125.
Kingston-upon-Hull, City and County of.—M.O.H. £1500.
Lancaster Royal Infirmary.—Jun. H.S. £130.
Leicestershire County Council.—Asst. County M.O.H. £700.
Liverpool, Royal Babies' Hospital, &c.—Res. M.O. At rate of £600.
London Hospital, E.—First Asst. and Reg. to Children's Dept. £300. Also Hon. Asst. Anæsthetist.
Manchester and District Radium Institute.—Asst. Radium Officer. £300–£500.
Manchester, City Education Committee.—Asst. School M.O. £600.
Manchester Royal Children's Hospital.—Sen. M.O. £300.
Manchester Royal Infirmary.—Asst. M.O. to Dermatologica Dept. £20.
Manchester, St. Mary's Hospitals.—Five H.S.'s. All at rate of £50.
Maudsley Hospital, Denmark Hill, S.E.—2nd. Asst. M.O. £625.
Middlesex County Council.—Ophthalmic Surgeon. £2 12*s.* 6*d.* per session.
National Hospital, Queen-square, W.C.—Registrar and Res. M.O. Each £200.
Newport, Mon., Royal Gwent Hospital.—Jun. Res. M.O. £135.
North-Eastern (Fever) Hospital, St. Ann's-road, Tottenham, N.—Res. Med. Supt. £1100.
Plymouth, South Devon and East Cornwall Hospital.—H.S. At rate of £100.
Queen Mary's Hospital for the East End, E.—Hon. Asst. Physician.
Queen's Hospital for Children, Hackney-road, E.—H.S. At rate of £100. Also Res. M.O. At rate of £200.
Radium Institute, Riding House-street, W.—H.S. At rate of £150.
Rotherham Hospital.—Cas. H.S. £150.
Royal Free Hospital, Eastman Dental Clinic, Gray's Inn-road, W.C.—Res. H.S. £100.
Royal London Ophthalmic Hospital, City-road, E.C.—Out-patient Officer. £100.
Royal Northern Hospital, Holloway, N.—H.P. At rate of £70.
Sheffield Children's Hospital.—Whole-time Registrar-Pathologist. £350. Also 3rd Res. M.O. At rate of £80.
Sheffield Royal Infirmary.—H.S., Ophth. H.S., Asst. Aural and Ophth. H.S. Each at rate of £80. Also Surg. Reg. £300.
Society of Apothecaries of London, Water-lane, Queen Victoria-street, E.C.—Examinership in Surgery.
Southport General Infirmary.—Jun. H.S. £125.
South Shields, Ingham Infirmary.—H.S. £150.
St. John's Hospital, Lewisham, S.E.—H.S. and Cas. O. Each at rate of £100.
St. Leonards-on-Sea, Buchanan Hospital.—Jun. H.S. At rate of £125.
St. Mark's Hospital for Cancer, Fistula, &c., City-road, E.C.—H.S. At rate of £75.
Sudan Medical Service.—Two M.O.'s. £E.720.
Swansea General and Eye Hospital.—H.P. £150.
Victoria Hospital for Children, Tite-street, Chelsea, S.W.—H.P. and H.S. Each at rate of £100.
Walsall, Manor Hospital.—Asst. M.O. £150.
Warrington Infirmary and Dispensary.—Jun. H.S. £175.
Warwick County Mental Hospital, Hatton.—Second Asst. M.O. £450.
Willesden General Hospital, N.W.—H.P. and H.S. At rate of £100 and £110 respectively.
Winchester, Royal Hampshire County Hospital.—H.P. At rate of £150.
Wolverhampton Royal Hospital.—H.S. and H.P. At rate of £125. H.S. At rate of £100. Also Hon. Fracture and Orthopædic Surgeon.

Births, Marriages, and Deaths

BIRTHS.

CUMMING.—On June 24th, at 56 Brunswick-square, Hove, the wife of Dr. John Cumming, of a daughter.

KERR.—On June 26th, at Bexhill, the wife of John Kerr, M.B., Ch.B., of a son.

LANGFORD.—On June 29th, at Cambridge-villa, Chiswick, W. 4, the wife of John C. C. Langford, M.R.C.S., of a son.

ROACHSMITH.—On June 21st, at Napsbury, the wife of Dr. C. E. Roachsmith, of a son.

ROBERTSON.—On June 25th, at The Green, Godstone, the wife of Douglas Robertson, M.R.C.P., of a son.

MARRIAGES.

HARDY—MANSFIELD.—On June 25th, at St. Michael's Church, Bournemouth, Edward William Dacre Hardy, M.C., M.R.C.S., L.R.C.P., to Dorothy Margaret, eldest daughter of Mr. and Mrs. Merton John Mansfield, of 7, Vernon-terrace, Brighton.

DEATHS.

BAILEY.—On Sunday, June 28th, suddenly, at Holly Bank, Headley, Hampshire, Henry Frederick Bailey, M.R.C.S., aged 86.

BUXTON.—On June 28th, his 76th birthday, at a nursing home, Dudley Wilmot Buxton, M.D., M.R.C.P., of Coldharbour, Boxmoor.

HAHR.—On June 28th, Carl Gustav Waldémar Hahr, M.R.C.S., L.R.C.P., of 50 Seymour-street, W. 1.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages and Deaths.

LIVERPOOL HOSPITALS.—The Royal Southern Hospital, Liverpool, last year admitted 3066 in-patients, and dealt with 25,726 out-patients; the latter figure is a fall of 527, mainly accounted for by the increasing number attending the massage and actinotherapy departments. In the theatre, now inadequate, there were 3603 operations. The average stay of each in-patient was 21 days, and the average weekly cost was £3 1*s.* 9¾*d.* Out-patients cost 6*s.* 3*d.* each. Although the cost of maintenance fell by £3485, the loss on the year's working was £9515. At the beginning of 1930 the debt to the bank amounted to £40,919, but it was reduced by £13,481 by the sale of securities representing the investment of free legacies in the early days of the institution.—The Lady Mayoress of Liverpool last week opened a new wing of the Liverpool Maternity Hospital which has cost £108,000, and was opened free from debt. It is proposed at a future date to add an isolation block and accommodation for medical students. There are now 85 beds and 75 cots, a lecture room, and other facilities for the teaching of nurses undergoing midwifery training, and a pathological laboratory. Last year there were 12,456 attendances at the hospital and 26,371 at the city's clinics.—A new nurses' home has been opened at the Robery Davies Nursing Home, West Derby, which was established six years ago for the reception of middle-class patients. The number of patients increased from 376 in 1928 and 461 in 1929 to 487 in 1930. The building of the nurses' home has made available 12 additional private wards.

NOTES, COMMENTS, AND ABSTRACTS

THE HEROIN HABIT.[1]

THE Council of the League of Nations last May appointed, for the purposes of a conference on the limitation of the manufacture of narcotic drugs and the traffic in opium, Prof. W. E. Dixon (University of Cambridge), Prof. Erich von Knaffl-Lenz (University of Vienna), Prof. M. Tiffeneau (Faculty of Medicine, Paris), and Dr. P. Wolff (Privat docent at the University of Berlin). The Technical Committee of the League thereupon asked the experts to report upon the following questions:—

1. What are the properties of diacetylmorphine (heroin) which make it particularly suitable to serve as a habit-forming narcotic drug, and to form the subject of illicit traffic?
2. What are the therapeutic advantages of diacetylmorphine as compared with those of morphia and other morphine derivatives?
3. Are the therapeutic properties of diacetylmorphine such that it cannot be replaced by other medicaments without ill-effects on the patient?
4. Are not the risks of diacetylmorphine for humanity incomparably greater than the advantages resulting from its therapeutic use?
5. Can the experts state what is the medical practice in each of the countries possessing a highly developed medical system, as regards the use of diacetylmorphine, and give their opinion as to the value of its use?
6. Is diacetylmorphine (heroin) an indispensable drug?

The experts reached a unanimous decision as to the above-mentioned questions, and their report is incorporated in the following document.

Report of the Expert Committee.

PREAMBLE.

As a preamble to the answer seriatim of the questions the experts found that morphine and its derivatives, whether habit-forming or not, possessed certain common characteristics and properties, but exhibited them in degrees so varying that it was necessary to refer to the variations before replying to the questions. The properties of the drug they find to be reduced to the following three principal actions:—

(a) *Analgesic and Euphoric Properties.*—These belong only to the habit-forming morphine alkaloids; they render these alkaloids *pain* relieving, and in certain people they alter psychical reflexes, so as to produce a feeling of *happiness and well-being.* The continual use of such alkaloids leads to addiction, and the addict acquires an irresistible craving and ever-increasing tolerance.

(b) *Depressing Properties on the Respiratory Centre.*—These are common to all the habit-forming morphine alkaloids, though different alkaloids show the effect in different degrees. This effect is manifested principally in the relief of cough and all painful affections of the respiratory system.

(c) *Depressing Properties on the Alimentary Canal.*—These are shown best with morphine, and render it valuable in the treatment of certain forms of colic.

The report continues: The *differences* between the various morphine alkaloids with regard to these properties are chiefly quantitative. These differences are *not necessarily in the same direction;* any one of these properties may be exaggerated, whilst another is at the same time hardly obvious. In *codeine* (methyl morphine), for example, the analgesic and euphoric properties (a) of morphine are very weak, whilst the (b) property is relatively little changed, and the (c) effect is a little weaker. In *heroin* the properties (a) and (b) are stronger, whilst the intestinal action (c) hardly exists.

The knowledge of these properties to the physician is of the utmost importance, not only in the treatment of drug addiction, but, what is much more important, the prevention of this condition. It is also an essential part of the doctors' armamentarium to be able to prescribe these drugs with the least risk, whilst providing for all the patient's requirements. Thus the choice of a drug like codeine for the relief of cough avoids the analgesic and euphoric action of morphine which in this case is useless or even harmful, as it involves unnecessary risks.

REPLIES TO THE QUESTIONAIRE.

1. Heroin is more powerful than morphine and its dose is smaller. Unlike morphine it may be readily taken as snuff. In the East it is occasionally smoked. Also in view of the smallness of its dose, trafficking is easier. Heroin euphoria is much more pronounced than that of morphine, and constipation does not occur in the addict—that is, the (a) and (b) effects are stronger and the (c) effect negligible.

2. Heroin has about double the action of morphine in the relief of pain (a). It is more effective than either morphine or codeine in the relief of cough (b). It does not constipate.

3. The properties of heroin, which render it popular with some physicians, can in most if not all cases be efficiently replaced by other morphine drugs. For the relief of cough codeine is a valuable substitute, though not so strong as heroin; dicodid has as powerful an effect on the respiratory centre as morphine, though less than that of heroin, and its addiction properties are less pronounced than those of the latter drugs. For the relief of pain in patients in whom it is undesirable to act on the bowels, heroin is better than morphine but dilaudide offers the same advantages. This alkaloid has much the same type of effect on the respiratory centre as heroin but is weaker; it has about the same influence as heroin in its pain-relieving properties, and, like heroin, has little effect on the alimentary canal. Furthermore, the euphoric effects of dilaudide are weaker than those of both morphine and heroin as gauged by withdrawal symptoms.[2]

4. We feel that the dangerous nature of heroin from the social point of view overshadows its therapeutic importance. The social dangers of heroin arise on the one hand from the great reputation this substance possesses among drug addicts and from the enormous illicit traffic which has arisen; on the other hand, they come from its characteristic habit-forming properties, which, from the medical point of view, are much worse than those of other habit-forming narcotic drugs. The effect of heroin is in the main to produce a change in personality as shown by an utter disregard for the conventions and the morals of civilisation. The disease progresses more rapidly than with any other habit-forming narcotic drug; all the higher faculties of mind, such as judgment, self-control, and attention, are weakened, and such people rapidly become mental and moral degenerates. The heroin habit is the most difficult of all to cure; sudden withdrawal of the alkaloid which, according to most authorities, is the best treatment for the morphine habit, may lead to cramps and convulsions and even to death from respiratory failure. But besides the difficulty of withdrawal, the after-convalescent treatment, both psychical and physical, is longer and more difficult with heroin, and relapse is the rule.

5. The opinion of the medical profession on the therapeutical value of heroin varies not only in

[2] With regard to the recently introduced dilaudide, Profs. Dixon and Tiffeneau desire to place on record that they have had no personal experience.

different countries but even in the same country. The medical consumption rates per head of the population for this substance, as shown by the League statistics, differ to such an extent that it suggests that its use is perhaps not unconnected with fashion. For example, there is a difference of 400 per cent. between the consumption rates for Great Britain and Germany, 4000 per cent. between those of Switzerland and France, and 4500 per cent. between Switzerland and Japan. Our attention has been drawn to the use made of heroin in the following sickness insurance societies (Krankenkassen) of two large cities in Central Europe. The Allgemeine Ortskrankenkasse der Stadt Berlin, with a membership of about 500,000, shows for 1927 a consumption of 0, and for 1928 a consumption of 3·24 g. If this figure were accepted as a basis of estimation, then for a group of 65,000,000 of inhabitants which represents the whole German population, the consumption should only total 425 g., whereas the actual consumption of this country was 36 kilos during the same year. The Krankenversicherunganstalt der Bundesangestellten of Vienna, which has also a membership of about 500,000, shows for the same period a total consumption of 144 g. Estimated on this basis, the total consumption of Austria would amount to 1930 g., whereas it was actually over 5 kilos. In considering these figures it should be borne in mind that these two groups of insured people belong to large urban centres whose narcotic consumption is usually higher than that of the rural populations, and that the members of these societies always represent that portion of the population which is best provided for as regards medical assistance. We have evidence that a large majority of the eminent pharmacologists and physicians throughout Europe and America are definitely opposed to the employment of heroin in medical practice.

6. In view of the evidence which we possess, and especially the fact that all the beneficial actions of heroin can in our opinion be obtained by one or other of the drugs mentioned, we believe that heroin can be entirely dispensed with. If the doctors in countries where heroin is used are afforded the opportunity of examining and testing clinically the morphine derivatives to which we have drawn attention, we feel little doubt that they may be induced to dispense with the use of heroin entirely.

A DEMONSTRATION OF THE SCHELLBERG APPARATUS.

A DEMONSTRATION was held at 55a, New Cavendish-street, London, on Thursday, June 25th, of this apparatus for colonic lavage, when a considerable assembly heard a description by Dr. Kerr Russell of the working of the apparatus while there was an informal debate on the medical claims for the treatment. From the mechanical point of view, the construction of the apparatus is ingenious and not difficult of manipulation, as was made clear by Dr. Russell's explanation. The object is to irrigate the cæcum and colon by the passage of a rubber tube by stages, and in the course of a varying number of sittings, along the complete length of the colon into the cæcum. The apparatus consists of three movable reservoirs for holding the different fluids used, a three-way tap for permitting the in-flow, and a tap for discharging the fluid siphoned from the colon into a container and thence to a soil pipe. Different thicknesses of rubber tubing are available. A central and large container holds two gallons of warmed distilled water. This is used for the first stage, to aid the catheter to be passed through the impacted masses right up to the cæcum. Arrived there, it is gradually withdrawn, and the contents of the two other smaller containers (of two quarts each) are gradually introduced during withdrawal. In this way the whole colon, from the cæcum to the anus, can be irrigated, it is claimed, with any substance prescribed. When the tube is completely withdrawn a natural evacuation of the bowel contents should follow, though this may not be obtained until after several sittings. The statement that the tube can be made to reach the cæcum has been supported by X ray photographs, when any medicament or disinfectant considered desirable can be injected, one of the commonest of these being a suspension of the anti-fermentative *Bacillus acidophilus*.

HINTS ON DIETS.

PRACTICAL guidance for the construction of diets suitable for use in the treatment of various diseases can be obtained from a handbook,[1] recently published, by Miss Simmonds, who is dietitian to the London Hospital. The principles underlying the selection of foods for use in special diseases and individual cases are briefly discussed, but most of the book is occupied by sample menus which have been found useful in clinical practice. The absence of controversial material is illustrated by the fact that no mention is made either in the text or in the index of diet in the treatment of nephritis, though sections are devoted to salt-poor and high protein diets. The feeding of the infant and young child forms a separate chapter. The practitioner should find this inexpensive volume of considerable assistance in his everyday work.

THE MECHANISM OF VISION.

THOSE who want to know something about the mechanism of vision and the common diseases of the eye without going deeply into the subject will find a little book by Dr. H. G. Merrill and Dr. L. W. Oaks[2] informative up to a point. The more difficult parts of the subject are not made very clear, partly because the diagrams are too scanty. Moreover, experts would object that the treatment of the whole subject is rather too dogmatic. It would hardly be possible adequately to treat such subjects as the relative functions of the rods and cones, the mechanism of accommodation, the circulation of the fluid within the eyeball, or the theory of colour vision in such an elementary book. The most that could truly be said would be that even among experts there is still considerable difference of opinion on most of these subjects. On the other hand, some useful information is given about squint in children with good advice on the necessity of early treatment, although the impression here given—that nearly all cases can be cured by appropriate glasses—is far too optimistic. The photographs demonstrating the types of ill-fitting spectacles commonly seen deserve unqualified praise, and perhaps this section is the most practically useful one in the book.

[2] Your Vision and How to Keep It. By H. G. Merrill, M.D., F.A.C.S., and L. W Oaks, M D. Second edition. London: G. P. Putman and Sons. 1931. Pp. 145. 6*s.*

HULL ROYAL INFIRMARY.—The 148th annual report records that last year 4100 in-patients were admitted (19·98 days' stay), who cost £2 13*s.* 1¼*d.* each. There were 15,644 new out-patients who were treated at an estimated cost of 4*s.* 0¼*d.* per head. The opening of the Sutton branch has added 100 beds.

PONY RACE MEETING FOR A HOSPITAL.—Recently a "pony race meeting" at Northolt Park was organised on behalf of St. Mary's Hospital, Paddington, with the Earl of Harewood as one of the stewards. All the entrance and parking money went to the hospital, and a large sum was collected on the course by students from the hospital.

EAST SUFFOLK AND IPSWICH HOSPITAL.—Last year this hospital was busier even than during the war, 5074 patients having been admitted with an average stay of 18·42 days, the lowest figure on record by reason of the full use made of the Bartlet Convalescent Home. There were 18,240 new out-patients. In-patients cost £3 2*s.* per week each, and out-patients 7*s.* 5½*d.*

ADDRESSES AND ORIGINAL ARTICLES

TOXIC JAUNDICE.*

By Sir William Willcox, K.C.I.E., C.B., C.M.G., M.D., F.R.C.P. Lond.,
PHYSICIAN TO ST. MARY'S HOSPITAL.

LECTURE II.—SYMPTOMS.

The symptoms of toxic jaundice may be grouped under two headings according to whether they are those of the causal agent or are due to its effect on the liver. Those of the causal agent are naturally of great variety; for example, in acute phosphorus poisoning there will be the acute symptoms of a burning sensation in the mouth and throat accompanied by those of acute gastro-enteritis. These symptoms may subside more or less within 24 hours and are then succeeded, either immediately or after an interval of a day or two, by jaundice and the grave symptoms due to hepatic necrosis. The jaundice due to quinoline derivatives such as atophan may be preceded by no premonitory symptoms or only by slight nausea or occasional vomiting.

Where the causal agent is biological in origin the symptoms of the primary infection, such as typhoid or malaria, will be manifest. In some cases of this type, such as epidemic catarrhal jaundice, the premonitory symptoms may be so slight as almost to escape notice.

The symptoms due to the effect on the liver of the toxic cause vary in intensity according to the amount of impairment of function of the liver cells. The jaundice may be slight or deep. The stools may be pale and clay-coloured for a varying period, ranging from a few days to weeks, and in mild cases the reduced bile-pigments (stercobilin) in the stools may be simply diminished in amount so as to give a yellow colour, paler than normal, for a few days. The urine may contain much bile-pigment, with some bile-salts and some urobilin. The van den Bergh reaction of the blood-serum is usually biphasic. The bile-pigment in the blood is greatly raised and the icterus index much increased. The lævulose-tolerance curve is abnormal and indicates hepatic function deficiency.

The symptoms caused by the increased bile-pigments are slight, since usually the deep jaundice does not persist long enough to give rise to the severe pruritus and skin irritation associated with prolonged mechanical obstruction of the main bile-ducts. The pulse-rate in toxic jaundice is usually quickened owing to the effect of the primary toxic cause. It does not constantly show the slow rate associated with the jaundice due to mechanical obstruction of non-toxic origin.

While the symptoms caused by the increased bile-pigment in the blood are mild, though the colour changes in the skin mucous membranes, urine, and stools are strikingly manifest, yet at any time during the course of an attack the very grave symptoms of auto-intoxication due to loss of hepatic function may develop. These will be considered under the heading of—

Acute and Subacute Necrosis of the Liver.

The term "acute yellow atrophy" has been applied to this condition and is still commonly used in text-books. The term "necrosis" is preferable because it is necrosis, not atrophy, which is the pathological change. The liver, while commonly much smaller in size than normal, may in acute cases be larger (vide Cases 1 and 6), so that the word atrophy, implying smallness of size, is not always appropriate. Then again, while the colour of the liver is usually yellow, in some of the more prolonged cases it may be reddish (vide Case 3), a condition to which the term subacute red necrosis is more accurately applied.

Necrosis of the liver has been classed as a special disease affecting the liver, but pathological studies during recent years show that it really results from some profound toxic cause, due either to an exogenous chemical poison or to the toxins of some toxic infection of biological origin, or to the poisons of the auto-intoxication of a disordered metabolism. It must be admitted that cases of necrosis of the liver are still met with in which the toxic cause cannot with certainty be determined.

The condition has become more frequent of late years. This may be accounted for by increased exposure to drugs having a selective toxic effect on the liver—e.g., arsenobenzol and quinophan.

MORBID ANATOMY.

It appears to me that the term necrosis of the liver should include all those cases where the liver cells have been so profoundly poisoned as to be functionally dead. Thus in an acute case of delayed chloroform poisoning, if death occurs early—i.e., within two or three days—the liver will be enlarged and yellow, and many of the liver cells will show distension with fat globules; if, however, death occurs later—say, in a week or so—the liver will be much shrunken in size owing to the absorption of the cells which previously showed fatty distension. In both of these cases the liver cells must have undergone death from the toxic effects to which they have been exposed.

Usually in necrosis of the liver life is sufficiently prolonged to admit of the shrinkage of the liver, which has been greatly enlarged in the early stages of the illness, so that commonly a much shrunken soft flabby liver is found on post-mortem examination; the weight may be reduced to one-half or even one-third of the normal, and the colour is yellowish or greenish-yellow, often with reddish areas due to subcapsular hæmorrhage. On section, the very acute cases—e.g., Cases 1 and 6—will show a bright yellow appearance, while the less acute cases, such as Case 3, show a yellow groundwork with red areas: subacute red necrosis, to which the old term red atrophy was applied.

The kidneys are enlarged, soft, and bile-stained, and often show small hæmorrhages on the surface. On microscopical examination marked degeneration of the epithelium is present and the tubular cells show marked fatty changes.

SYMPTOMS.

The symptoms of "necrosis of the liver" are dramatic, and run a characteristic and usually rapidly fatal course. Various terms have been used to describe this condition. "Icterus gravis" has been commonly adopted; its disadvantage as a name is that icterus may be slight or even absent in the very acute cases. Some writers have suggested the word cholæmia; this again is unsatisfactory because excess of bile in the blood, as seen in cases of stricture of the common bile-duct, does not per se produce toxic symptoms. Patients with complete obstruction of the bile-duct may live for months without symptoms beyond those of the skin irritation due to the increased bile content in the blood. I would suggest as more suitable for the toxic condition caused by necrosis of the liver the term hypohepatism. This expresses the fact that there is loss of liver function, which is the undoubted cause of the grave symptoms. The term corresponds to similar terms in use expressive of loss of function of the respective organ, such as hypothyroidism, hypopituitarism, and hypoadrenalism.

---

* The Lumleian Lectures delivered before the Royal College of Physicians of London on March 19th, 24th, and 26th, 1931. Lecture I. appeared in THE LANCET of July 4th.

Necrosis of the liver is ushered in by nausea, vomiting, and gastric irritation; the tongue is furred, dry, and tremulous; there is a feeling of mental anxiety and sense of impending disaster; the patient becomes restless, quarrelsome, and difficult to manage. Headache and photophobia are sometimes present. Twitchings of the muscles often occur; the knee-jerks become brisker than normal. An extensor plantar reflex may occur at this stage, and is of very serious portent. Transient squint or involuntary ocular movements may occur, and in some cases marked head retraction. The nervous symptoms accompanying the development of acute hepatic necrosis may in some cases very closely resemble those of meningitis, the differential diagnosis being readily determined by the condition of the cerebro-spinal fluid removed by lumbar puncture.

These premonitory symptoms may last from a few hours to a few days and are then commonly succeeded by delirium, drowsiness, and stupor, passing into coma. Cheyne Stokes's breathing is often marked. The temperature commonly rises, and may reach a high level, of 104° or more, a few hours before the end. Hæmorrhages are very common, such as severe hæmatemesis, epistaxis, bleeding from the gums, rectal bleeding, hæmaturia, purpuric patches on the skin, or vaginal hæmorrhage.

Convulsions may develop during the stage of stupor or coma. The plantar reflexes are often, but not always, extensor in the stage of coma. The pulse becomes rapid and feeble. The urine usually contains albumin and some granular casts, and often red blood corpuscles. Leucine and tyrosine crystals, so often described in the text-books as characteristic of this condition, are by no means common in my experience.

Death occurs at varying intervals after the onset of symptoms, usually within three or four days, but it may be earlier where severe hæmorrhages such as hæmatemesis take place.

TREATMENT.

Treatment resolves itself into the treatment of cases: (1) during the stage of toxic jaundice when the jaundice is latent or developed; (2) during the stage when definite symptoms of hepatic inefficiency due to necrosis of liver have developed.

(1) Removal of the toxic cause should be immediate. The approach of jaundice may often be detected by the quantitative van den Bergh or icterus index test.[13] Alkalis, such as citrate of soda, bicarbonate of soda, and citrate of potash, in full repeated doses, should always be administered.[14 15] Saline aperients, such as magnesium and sodium sulphate, are of value in promoting the emptying of the gall-bladder and the free flow of bile. Glucose should be given freely.[16 17] It appears to act by providing the liver cells with glycogen which protects them against the action of poisons. Glucose should be given before the administration of any drug having a toxic action on the liver, such as an anæsthetic or an arsenobenzol compound. An ounce may be given with coffee or fruit juice two hours previously. If toxic jaundice has developed, the free administration of glucose should be continued, and subcutaneous or intravenous methods may be resorted to. I have used liver extract with benefit in several cases where a mild and persistent jaundice has occurred as the result of some chronic intestinal infection of bacterial origin.

Diet should be arranged so that as little burden is thrown on the liver cells as possible. Protein should be greatly reduced and fatty foods eliminated. Fresh fruit juices, glucose, honey, raisin tea, whey, fruits, vegetables, and carbohydrate foods should form the main portion of the dietary.

(2) Where the grave symptoms of acute necrosis of the liver are beginning, active treatment should be adopted without delay. Glucose in 5 per cent. or 10 per cent. solution in normal saline given subcutaneously or intravenously is of value.

Alkalis, such as citrate of soda ʒi and bicarbonate of soda ʒss, every three hours, should be given by the mouth. By rectum bicarbonate of soda 2 per cent. and glucose 5 per cent., as much as can be retained, should be given six-hourly. One or two pints of bicarbonate of soda 1 per cent., with glucose 5 per cent., may be given intravenously with advantage.

Where hæmorrhages have begun, calcium chloride 1 per cent. may be given intramuscularly or intravenously in one dose of 10 to 20 c.cm., and at the same time parathormone in a dose of 10 units may be given subcutaneously. When coma has developed it may be advisable to perform lumbar puncture and draw off 10 to 20 c.cm. of the cerebro-spinal fluid.

Active treatment in the early stages of hypohepatism has not infrequently led to an arrest of the symptoms and subsequent recovery. When the stage of coma has arrived recovery has not often occurred, though a few instances of success have been seen after the adoption of treatment on the above lines.

Classification of Toxic Jaundice.

Toxic jaundice may be best classified according to its causation:—

1. *Chemical poisons*—viz., the halogen group of organic compounds, which includes tetrachlorethane, carbon tetrachloride, chloroform, ethyl chloride, ethyl bromide, trichlorethylene, and tribromethyl alcohol (Avertin).

Arsenobenzol derivatives, such as salvarsan, kharsivan, neo-salvarsan, novarsenobillon, and gallyl.

Quinoline derivatives, examples of which in common use are: quinophan (phenylquinoline carboxylin acid, also known under the names of atophan, agotan, cinchophen, and phenoquin), atophanyl, atoquinol.

Aromatic organic compounds, such as trinitrotoluene, dinitrobenzene, dinitrophenol, picric acid, phenylhydrazine, toluylene diamine, and acriflavine derivatives.

Inorganic arsenic compounds, including arseniuretted hydrogen.

Antimony compounds, inorganic and organic, both of which are much used in the treatment of tropical diseases, such as kala-azar and trypanosomiasis; phosphorus, alcohol, lead, and synthalin.

The above list is of necessity very incomplete, since the number of chemical poisons having a toxic action on the liver is very large indeed. *In this group must be included* mushroom poisoning and snake bite.

2. *Bacterial poisons*, such as the toxins from enteric and paratyphoid fever, parenteric infections, food poisoning, influenza, pneumonia, streptococcal infections, pyogenic infections, and epidemic catarrhal jaundice.

3. *Protozoal poisons*, such as the toxins from syphilis, relapsing fever, yellow fever, spirochætosis ictero-hæmorrhagica, malaria, amœbic dysentery, typhus fever, and kala-azar.

4. *Auto-intoxications*, such as the toxæmias associated with pregnancy, recurring vomiting (acidosis), uræmia, and acholuric jaundice.

1. Chemical Poisons.

THE HALOGEN GROUP OF ORGANIC COMPOUNDS.

The effect of chloroform on the liver in causing delayed poisoning, which is usually accompanied by jaundice, has been known for many years.

It has been found that weight for weight, compared with chloroform, carbon tetrachloride is four times more toxic, and that tetrachlorethane and trichlorethylene are respectively 2·8 and 1·36 times more toxic.[18] These figures must represent the relative toxic action of these substances on the liver cell.

Carbon tetrachloride is extensively used in the tropics as a remedy for ankylostomiasis. Several cases of death from acute necrosis of the liver from the taking of the drug in this way have been recorded, and cirrhosis of the liver may result from continued repeated doses.[19] Fatty degeneration of the liver in animals has also been demonstrated.[20]

Chloroform.—After the administration of chloroform as an anæsthetic toxic jaundice (delayed chloroform poisoning) will occasionally develop. A series of cases in 1911 at a children's hospital in London attracted much attention.[21] Dr. R. S. Frew[21] in 1912 remarked on the frequency of acetonuria in children admitted to hospital, and pointed out that this usually commences 12 hours after admission and continues for three days. He regarded the presence of acetonuria as a sign that there was danger from delayed chloroform poisoning should this substance be given as an anæsthetic. The free administration of glucose rapidly caused a disappearance of acetonuria.

CASE 12.—As a typical case of delayed chloroform poisoning might be quoted that of a boy, aged 12, admitted to St. Mary's Hospital in February, 1916, and operated upon for appendicitis under chloroform anæsthesia. He recovered satisfactorily from the immediate effects of the operation. Three days after the operation he became drowsy, and vomiting occurred on several occasions; definite but not deep jaundice now developed. The drowsiness deepened into stupor and coma, and death occurred five days after the operation and 48 hours after the symptoms of hypohepatism (icterus gravis) commenced.

On post-mortem examination by Sir Bernard Spilsbury, intense degeneration of the liver cells was found, with marked fatty deposition.

In three recent cases of delayed chloroform poisoning occurring in association with difficult labour, on which the post-mortem examinations were carried out by Dr. Newcomb, death occurred respectively three days (Case 6), four days, and four days after the administration of the anæsthetic. In these cases the toxæmia of pregnancy no doubt accelerated the fatal termination. In each case post-mortem examination revealed the typical acute central necrosis of the liver cells associated with fatty degeneration in the periphery of the lobules. Interesting work on the action of chloroform on the liver (dogs and rats) has been published by R. M. Anderson,[22] who finds that it causes central necrosis and fatty degeneration.

In applying these results to human beings it must be borne in mind that the regenerated liver tissue is abnormal in its anatomical structure—i.e., that masses of regenerated liver cells are not grouped into true lobular structure with central and peripheral veins. This is well shown in Cases 2 and 4. There is, therefore, in human subjects a great risk of the development of portal obstruction when recovery has taken place with regeneration of liver cells following the action of toxic agents on the liver. Clinical experience supports this view, as is seen in several cases to be described.

Two unusual cases of toxic jaundice from chloroform have come to my notice.

CASE 13.—A scientific man, aged 50, first seen in September, 1919, the subject of recurring colds, conceived the idea that chloroform inhalations would kill the microbes in the mucous membrane of the air passages. He practised inhalation of chloroform in slight but repeated doses daily for six months. Jaundice then developed with enlargement of the liver, followed by the typical signs of cirrhosis with ascites. Death occurred after 18 months from this cause. There was no doubt that the chloroform inhalations were an important contributing factor in causing the cirrhosis, and also that they had given rise to an addiction habit.

CASE 14.—A lady, aged 44, seen in November, 1930, had for six months been in the habit of putting chloroform in her bath. She had been told that this would reduce her weight by removal of fat. At the end of this period, during which upwards of 124 oz. of chloroform had been used, the patient developed slight toxic jaundice, due no doubt to the inhalation of chloroform vapour during the baths. A good recovery was made after cessation of use of the drug and suitable treatment. The patient said that her weight was reduced by 1½ stone.

Tetrachlorethane, a colourless liquid smelling like chloroform and having a specific gravity of 1·614 and a boiling point of 147°, has the property of being a solvent of cellulose. It was used before the war for the preparation of a solution of cellulose which was applied to the canvas wings of aeroplanes, to give them stability and make them air- and water-proof. The solution, which also contained acetone, alcohol, and benzene, was known by the aeroplane workers as "dope." Its intensive use immediately before and in the early part of the war led to the great exposure of the workers to its vapour.[23] [24] [25]

CASE 15.—On Nov. 15th, 1914, I saw the first case in this country of tetrachlorethane poisoning. The patient came to St. Mary's Hospital and was seen by me in the out-patient department. He gave a history of employment in an aeroplane factory since August 8th, 1914, during which time he had been exposed to the vapour of the dope which he had used for varnishing the wings. He said that ten other workers were similarly affected and that the dope smelt like chloroform; also that others who did not use the dope had similar symptoms.

On Oct. 24th he suffered from jaundice, epigastric discomfort, nausea, and vomiting in the mornings. At my examination marked jaundice was present; the patient was obviously ill, with a temperature of 99·5°, a pulse-rate of 96, an enlarged liver, pale stools, high-coloured urine, and furred and dry tongue.

The diagnosis of toxic jaundice, due to some substance of the chloroform group of poisons, was made. The patient went into the Middlesex Hospital, where he developed ascites, and died on Nov. 26th, 1914. An inquest was held by the late Mr. Luxmore Drew and a post-mortem examination made by Sir Bernard Spilsbury, who found a condition of subacute necrosis of the liver which he attributed to some toxic poison.

Investigations carried out by me on the aeroplane dope showed that the toxic agent was tetrachlorethane. Animal experiments conducted by Spilsbury and myself showed that when rats were exposed to the inhalation of vapour of the dope, or to tetrachlorethane vapour, for eight hours a day for a week, fatty degeneration of the liver and definite toxic jaundice developed; fatty degeneration of the kidney cells also occurred. It was thus established that the cause of death was tetrachlorethane poisoning due to the inhalation of the vapour of the aeroplane cellulose varnish.

A considerable number of cases occurred in aeroplane factories in 1914 and the early part of 1915. Many of these proved fatal, with typical post-mortem signs of necrosis of the liver.[24] [25]

When I visited the aeroplane factory on Dec. 4th, 1914, many of the workers were suffering from malaise associated with nausea, biliousness, constipation, anorexia, and headache, due to toxic latent jaundice, and some of them showed slight icterus of the sclerotics. These workers had not yet gone on the sick-list, but they were in the preliminary stage of the severe toxic jaundice which occurred after further exposure to the poisonous vapour. Tetrachlorethane produces a deep jaundice of toxic type not associated with anæmia. Its action is on the liver cells and not on the blood; in other words, the jaundice is hepatogenous, not hæmolytic. It was found in 1916 that its use could be abolished, since amyl acetate, which is less poisonous, proved to be a good solvent of cellulose and was used in its place.

Ethyl chloride is probably the least toxic of the halogen group of organic compounds; nevertheless a few fatal cases of delayed poisoning have been recorded by Guthrie from its use as an anæsthetic.[14]

Avertin or tri-brom-ethyl alcohol, a white crystalline powder, has recently been introduced as an anæsthetic. It undoubtedly has a marked toxic action on the liver and, though no cases of toxic jaundice have yet been recorded as far as I know, the possibility of danger must be borne in mind and the same preliminary precautions as to diet and acetonuria taken as with chloroform anæsthesia.

Dr. Parsons, who is at present carrying out experiments on its toxicity, has given me permission to record this recent experiment.

A rabbit weighing 1·1 kg. was given subcutaneously 26 c.cm. of 0·2 per cent. solution of crystalline avertin. This represents a normal anæsthetic dose of 0·475 g. per kg. Anæsthesia occurred 80 minutes after administration. The animal was killed 96 hours after administration. Dr. R. Williamson, of Cambridge, made the post-mortem examination. The liver was at once removed. No macroscopic changes were present. On staining with hæmatoxylin and Sudan III. (frozen sections) quite marked fatty degeneration was found in the central and intermediate zones of the lobules (see Plate, Lecture I., Fig. VII.). (×60.)

It seems probable that the toxicity of the halogen organic compounds increases with the increase of the halogen element in the molecule—e.g., tetrachlorethane is more toxic than chloroform or ethyl chloride. The bromine element probably makes a more toxic compound than the analogous chlorine derivative, and the iodine element a more toxic compound than the bromine compound; for example, iodoform is more toxic than bromoform, and bromoform than chloroform, per weight of absorbed drug.

Arsenobenzol Derivatives.—The original compound of this group was salvarsan (dioxydiamidoarsenobenzol hydrochloride), which was introduced by Ehrlich in 1910. His neosalvarsan (1912) was a modification more convenient for administration. In 1914, as a war emergency, kharsivan and neokharsivan were prepared in this country. These substances were identical in chemical and physical constitution with salvarsan and neosalvarsan respectively and had equally valuable therapeutic properties. All the arsenobenzol derivatives have a toxic action on the liver, and great care is required in their use.

Case 16.—A female, aged 23, suffering from secondary syphilis, was on Nov. 30th, 1911, given 0·4 g. of salvarsan and on Dec. 4th, 1911, the same dose. On Dec. 7th epileptiform convulsions occurred, followed by coma and death. The urine contained albumin. Post-mortem examination by Spilsbury showed marked necrosis of the liver. Toxicological analysis by J. Webster and myself showed arsenic in large amount (0·83 mg. As_2O_3 per 100 g. in the liver).

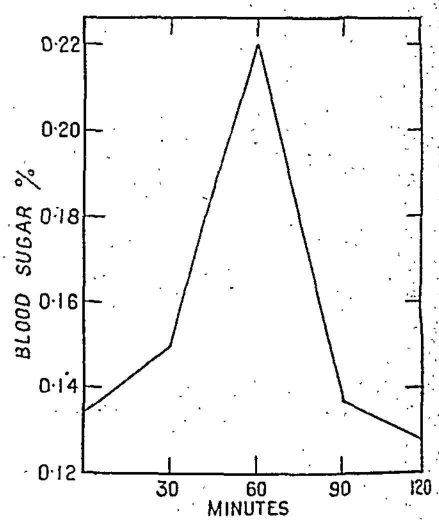
Case 17.—A male adult, with tertiary syphilis and gummata of the legs, was given 0·6 g. of salvarsan on May 9th, 1914. No toxic symptoms occurred. On May 23rd 0·6 g. of salvarsan was given. On May 25th aphasia occurred followed by coma and convulsions and death. Post-mortem examination by Spilsbury showed advanced central necrosis of the liver cells. Toxicological analysis by Webster and myself showed much arsenic in the liver (1·1 mg. of As_2O_3 per 100 g.).

In these and similar cases no arsenic was found in the brain, so that the acute nervous symptoms were not due to the action of arsenic on the brain but to the acute auto-intoxication (hypohepatism) following on the extensive necrosis of the liver. Death occurred before there was time for jaundice to develop.

Fortunately acutely fatal cases of the above type are at the present day of extreme rarity. This is partly due to the careful testing for toxicity of the batches of arsenobenzol compounds before they are placed on the market in this country. This duty has been entrusted to the Medical Research Council since 1915. It may be mentioned that for some unexplained reason arsenobenzol compounds may vary greatly in their toxicity though chemically they may pass the necessary tests.

At the present time in the treatment of syphilis it is realised that for an effective cure large quantities of arsenobenzol are required—very much greater than those contemplated by Ehrlich. The patient can be protected by taking glucose before the doses. Any idiosyncrasy to the drug is an indication for its avoidance and the use of some other method of treatment, such as mercury or bismuth. The doses of arsenobenzol should be spaced out. I have shown that, after an intravenous dose of arsenobenzol, arsenic can be detected in the urine for at least 14 days; therefore if full doses are given this interval should be allowed between the doses.

FIG. 2.



Lævulose-tolerance curve in a case of jaundice due to galyl (dose of lævulose 50 g.). The urine passed at 120 minutes contained no reducing substance.

A typical case of arsenobenzol jaundice which was under my care was:—

Case 18.—A man, aged 44, was admitted to St. Mary's Hospital on July 18th, 1922. He had been attending hospital for tertiary syphilis and glossitis. Galyl injections of 0·25 g. had been given on May 1st, 8th, 22nd and 29th, and on June 6th and 19th. On July 4th jaundice developed. The liver was enlarged, reaching 2 in. below the right subcostal border. On July 20th the lævulose-tolerance test showed a marked reaction for hepatic inefficiency (Fig. 2). The stools were pale for four days after admission, but afterwards became normal in colour. The liver shrank to the normal size, the jaundice disappeared, and a good recovery was made.

Quinoline Derivatives.—These are largely used at the present time for the treatment of gout and chronic rheumatic conditions. The commonest preparation is quinophan (phenyl quinoline carboxylic acid), also known by the trade names atophan, agotan, cinchophen, and phenoquin; it was introduced in 1912. A preparation on the market known as "gorum" cachets contains an appreciable amount of atophan. Atophanyl is a liquid containing equal proportions of sodium atophan and sodium salicylate in solution; it is given intravenously and intramuscularly. Atoquinol is the allyl ester of quinophan. It is a solid and is used for oral administration.

None of these drugs is on the Poisons Schedule and no restriction exists on their sale.

The occurrence of toxic jaundice after the use of quinophan and the above-mentioned group of substances has been noted by many observers for some years.

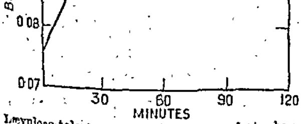
In the *British Medical Journal* in 1926[27] letters appeared from Dr. W. Langdon Brown, Dr. Geoffrey Evans, Dr. C. Worster-Drought and myself calling attention to the numerous cases of toxic jaundice, some of them fatal, which had resulted from the use of this group of drugs. Similar observations have been made in *America*.[28] Mr. H. *Dickson* Wright tells me that he attended a clinical meeting at the Mayo Clinic in August, 1930, when five cases of deep jaundice following the taking of quinophan were exhibited. Such jaundice lasts for several weeks. For some days it is obstructive in type, the stools being clay-coloured and the urine containing excess of bile-pigments. The gall-bladder is *not* enlarged, the obstruction being intrahepatic and due to the hepatitis caused by the drug. The liver is considerably enlarged during the jaundice stage, but the spleen is not. The jaundice persists for many days after the stools regain their normal colour; the van den Bergh reaction is marked and biphasic. In some cases *premonitory warning symptoms occur.* In a fatal case quoted from the Mayo Clinic reports, marked pruritus occurred during the administration of the drug and was controlled by soda baths.

The following is a typical case which was seen by me in consultation with Dr. D. Y. Buchanan at the Ealing Hospital:—

CASE 19.—A man, aged 35, was admitted to hospital on Feb. 4th, 1929. Two tubes of atophan tablets had been taken in November and December, 1928. On Jan. 20th jaundice developed and became deep, and lasted until March 20th, 1929. The stools were pale for the first week and afterwards became normal in colour. The urine contained bile-pigments and bile-salts. The van den Bergh reaction on Feb. 6th was biphasic and 75 units. The patient made a good recovery and is in good health at the present *time.* There was a period of at least four weeks between the cessation of the taking of the atophan and the onset of the jaundice.

CASE 20.—As an example of fatal cases may be quoted that *of a* man, aged 69, who took atophan, grs. 5 t.d.s., *for* six days from July 10th to 16th, 1925. On August 8th he developed rapidly deepening jaundice. The liver was enlarged. The stools were pale for a few days only. On August 31st typical symptoms of acute necrosis of the liver occurred, the patient dying on Sept. 5th. During the last few days the urine contained a trace of albumin and epithelial and granular casts.

FIG. 3.



Lævulose-tolerance curve in a case of atophan jaundice due to taking "Gorum cachets" (dose of lævulose 50 g.).

Two cases of toxic jaundice following the taking of "Gorum" cachets have recently been under my care.

CASE 21.—A woman, aged 70, developed on July 7th, 1930, quickly deepening jaundice about three weeks after a course of Gorum cachets (two daily for six days). The jaundice was of toxic type. The van den Bergh reaction was biphasic and 160 units on July 29th. Ascites developed on August 19th, severe hæmatemesis on Sept. 8th, and death occurred on the 10th. There was no history of alcoholism in this case. The hepatic cirrhosis was no doubt the result *of the hepatitis following* the quinophan in the Gorum cachets.

CASE 22.—A woman, aged 52, took Gorum cachets t.d.s. from Nov. 12th to Dec. 3rd, 1930, and also t.d.s. from Dec. 10th to 24th, 1930. On Feb. 1st, 1931, jaundice developed and rapidly deepened. Vomiting occurred *Feb. 4th.* No abdominal pain. On Feb. 28th, 1931, the liver was enlarged, reaching 2 in. below right subcostal border; surface smooth. Urine contained much bile-pigments and some bile-salts; stools pale Feb. 25th–28th; afterwards colour returned and became *normal on March 6th.* On March 4th, 1931, van den Bergh test was direct positive bilirubin, units 98. The lævulose-tolerance test (Fig. 3) showed a marked positive reaction for hepatic insufficiency. Dr. J. D. Robertson kindly carried out the investigations in *this* case. The patient has been suffering from typical toxic jaundice. On March 13th the liver was reduced in size, the jaundice was clearing, and the patient making good progress towards recovery. On the 23rd she was well apart from some remaining jaundice, the liver being normal in size.

The striking feature about the quinophan cases of toxic jaundice is the marked depth of the jaundice and the absence of any marked anæmia. A marked hepatitis seems to be caused and there is danger of obstructive cirrhosis. It appears that in these cases age is an important predisposition to severity of action of the drug, and for this reason I think that there is danger in its use in persons over the age of 50.

AROMATIC ORGANIC COMPOUNDS.

Trinitrotoluene.—This substance, T.N.T., was used very largely during the war as an explosive, and munition workers were employed on filling shells with it. Numerous fatal cases of toxic jaundice, due to the necrosis of the liver caused by the substance, have been recorded, and several such cases have been under my personal observation.

Two very prolonged cases are worthy of record.

CASE 23.—A woman, aged 32, was admitted into St. Mary's Hospital on July 16th, 1926, under my care. She *had been employed* in a T.N.T. factory in 1915 and had developed toxic jaundice while working there. She had been in poor health since, suffering from abdominal discomfort and nausea. The liver was enlarged, and there was slight jaundice. She was readmitted to hospital on Nov. 9th, 1926. The *lævulose test showed hepatic deficiency.* Ascites developed, and paracentesis was performed on Nov. 20th and Dec. 16th. She was readmitted to hospital on Sept. 8th, 1927, with ascites and jaundice; paracentesis yielded 31 pints. She was readmitted on Oct. 22nd, 1927, with ascites and jaundice; paracentesis yielded 22 pints. She died in December, 1927. There was no history of alcoholism or syphilis. The cause of death was progressive hepatitis set up by T.N.T. poisoning in 1915.

A similar remarkable case (Case 9) was kindly reported to me by Dr. Pulvertaft, of St. Thomas's Hospital. A woman suffered from toxic jaundice while working in a T.N.T. factory in 1918. She developed ascites in December, 1927, and died early in *February*, 1928.

Post-mortem examination showed chronic hepatitis with cirrhosis and more recent yellow atrophy. The sections on microscopical examination showed much fibrosis and many giant cells due to the chronic hepatitis, and also necrosis of the remaining liver cells. In this case the cause of death was no doubt progressive hepatitis set up by the T.N.T. poisoning.

As mentioned in my first lecture cases of jaundice have followed T.N.T. poisoning after an interval of as long as nine months from last exposure.

Dinitrobenzene, dinitrophenol and *picric acid* have all *given rise* to toxic jaundice of similar type to that caused by trinitrotoluene.

Toluylenediamine and phenylhydrazine have been used for the production of toxic jaundice in dogs for research purposes. *Dr. William Hunter showed that* toluylenediamine in dogs had a specific effect on the intrahepatic bile capillaries, causing intrahepatic obstruction and deep jaundice. These experiments have an important bearing on the jaundice following the atophan group of poisons and the arsenobenzol compounds.

Inorganic Arsenic Compounds.—In a paper read before the Medico-Legal Society in July, 1922,[29] I pointed out that toxic jaundice was common in acute arsenical poisoning. Recent examples of this have been furnished by the symptoms of the deceased in the Armstrong case, the Greenwood case, and the Pace case.

Arseniuretted Hydrogen.—This gas is intensely poisonous; it destroys the red blood corpuscles and also produces necrosis of the liver cells. A very interesting and detailed account was published by Dr. J. Dixon Mann and Dr. J. Grey Clegg[30] of five fatal cases in which marked hæmorrhage (hæmaturia, &c.) occurred with jaundice and death from acute necrosis of the liver.

Antimony compounds, inorganic and organic, may cause toxic jaundice in a similar manner to the corresponding arsenic compounds.

Phosphorus is an intense liver poison, causing death rapidly from acute necrosis of the hepatic cells with toxic jaundice. Case 1 is a typical example.

ALCOHOL.

It is universally agreed that the action of alcohol in large doses causes marked fatty degeneration of the liver cells. In some cases the enlargement of the liver is great and the organ of a marked yellow colour, the appearance resembling that seen in fatal cases of acidosis, or delayed chloroform poisoning in children. In this type of case vomiting may be a very marked feature, so much so as to give rise to the suspicion of irritant poisoning.

An interesting case of this type was investigated by me on behalf of the Home Office in 1909.

CASE 24.—A man, aged 50, had been ill in bed for four weeks in the country; the chief symptoms were vomiting of a very persistent character and some diarrhœa. Slight jaundice was present. Death resulted after four weeks' illness, the patient passing into stupor delirium and coma with the usual symptoms of hypohepatism. A few days before death the urine was sent to a local pharmacist for analysis, and very large mirrors of arsenic were obtained after the application of the Marsh-Berzelius test. The wife was suspected of administering arsenic, and the stage was set for another Maybrick case.

The viscera were examined by me. No arsenic was present in any of them. The liver was very enlarged, and had the usual canary-yellow appearance associated with a very marked degree of fatty change. It was typical of the fatty liver found in some cases of alcoholism. The history showed that the deceased had consumed large quantities of whisky for some time and that this consumption had continued throughout his terminal illness. An inquest was held and I was submitted to a severe cross-examination by the coroner. It was clear that the arsenic found in the urine had arisen from the use of impure chemicals containing arsenic. The suspicion of arsenical poisoning was effectively disposed of by my evidence. The cause of death was liver degeneration from alcoholism.

In a few cases acute alcoholic excess has given rise to acute necrosis of the liver with its accompanying group of fatal symptoms. It is clear that in most cases of hepatic cirrhosis alcohol plays a predisposing part, permitting the passage of toxins of bacterial origin through the gastro-intestinal mucous membrane and so on to the liver. It appears that it is these toxins and not the alcohol which cause the progressive hepatic fibrosis.

It must also be borne in mind that cirrhosis of the liver not infrequently occurs in persons who have never taken alcohol. There are many chemical agents other than alcohol which will cause cirrhosis of the liver and also many infective causes, such as chronic intestinal infection, syphilis, and bilharziasis. This being so, it cannot be too strongly emphasised that in cases where death is due to cirrhosis of the liver the cause of death should be regarded as "natural" unless the contrary is proved. The custom of holding an inquest as a matter of routine in cases of cirrhosis of the liver is, in my opinion, contrary to the most modern views of pathological knowledge regarding the cause of this condition, and is a custom which should be discontinued. Needless publicity of a character most painful to the relatives of the deceased is thereby caused to no purpose.

It must, however, be admitted that occasionally a rapidly acute cirrhosis of the liver of virulent type may be set up by alcoholic drinks. Several such cases have been recently reported where death has resulted from what must be regarded as alcoholic poisoning. The drink in question is known as Lisbon wine, and is undoubtedly a very toxic form of alcohol which resembles port wine in colour, though not in taste. It is known in the south and east of London as Red Lizzie. It causes very acute alcoholic intoxication and many deaths have resulted from its consumption. Mr. A. Douglas Cowburn, H.M. coroner for South London, has informed me that he has recently held inquests on several fatal cases of alcoholic poisoning from Lisbon wine.

One such case was under my care at St. Mary's Hospital recently and is worthy of record.

CASE 25.—A male, aged 34, married, was admitted on May 5th, 1930. On admission toxic jaundice and ascites were present. The patient stated that for the last six months he had drunk a bottle of Lisbon wine a day; before that time he had been a beer drinker for four years. This statement was confirmed by his wife. The van den Bergh reaction was biphasic, the icterus index was 54 units, and the blood-urea 21 mg. per 100 c.cm. The Wassermann reaction was negative. On May 24th paracentesis abdominis yielded 15 pints; the fluid was of greenish colour and turbid. On May 28th paracentesis yielded 10 pints, and on May 31st 10½ pints. On June 6th the abdomen was opened by Prof. C. A. Pannett and a condition of acute hepatic cirrhosis was found; the ascitic fluid contained streptococci which had no doubt set up a mild infection from the intestinal organisms. No bowel perforation was present.

This case was obviously one in which official inquiry was required. It was reported to the coroner and post-mortem examination by Sir Bernard Spilsbury showed that a very acute active cirrhosis of the liver was the cause of death.

This case was one of acute cirrhosis of the liver caused by the consumption of a very toxic and bad form of alcoholic drink which was taken right up t the time of the onset of the symptoms. It is a example of the type of case of cirrhosis of the liver which should be reported to the coroner and for which a death certificate should not be given.

In my opinion the decision as to whether a fatal case of cirrhosis of the liver should be regarded as being due to natural causes or the direct result of alcoholic poisoning can only be decided upon by the medical practitioner in charge of the case, and he would be wise, if necessary, to obtain expert medical advice on the point.

VARIOUS OTHER POISONS.

Lead.—Lead poisoning, as ordinarily occurring from industrial or accidental causes, is not definitely associated with toxic jaundice. The intravenous use of lead preparations in the treatment of cancer has shown that toxic jaundice is a danger to be looked for and guarded against.[31]

Synthalin.—An alkylguanidine derivative which was introduced a few years ago as a possible substitute for insulin in the treatment of diabetes has been found in some cases to have a definite toxic action on the liver, and toxic jaundice has been observed after its use.

Mushroom Poisoning.—Poisonous fungi eaten in mistake for edible mushrooms produce acute gastro-intestinal irritation and intense degeneration of the liver cells with marked fatty change in them. The symptoms are those of acute auto-intoxication due to arrest of liver function and are often associated with hæmorrhages. Toxic jaundice is sometimes seen, but death may occur before it has time to become manifest. The post-mortem appearance of the liver resembles that of the enlarged fatty liver seen in phosphorus poisoning or in the delayed chloroform poisoning of children. Common poisonous varieties of mushrooms are *Amanita phalloides*, *A. verna*, and *A. muscaria*.

Snake Bite.—The venom of snakes of the viper order causes a very marked local extravasation of blood which may involve a large area around the bite. Local and sometimes general jaundice may occur after the bites of such snakes.

CASE 26.—On May 30th, 1930, I saw an interesting case of adder bite in a boy, aged 8, who had been bitten on the right middle and ring fingers the previous day. Much faintness and collapse occurred a few minutes afterwards and for 12 hours vomiting and diarrhœa occurred. Blebs containing pink serum appeared at the site of the bites. The whole of the right hand, forearm, arm, and right side of the chest became swollen with blue mottled areas due to superficial hæmorrhages. The swollen area after three days took on a yellowish colour and the swelling gradually subsided. Local but no general jaundice resulted. The boy made a good recovery.

In this case the blood was tested on June 3rd by Dr. Alexander Fleming. The coagulation time was normal and the fragility test of the red corpuscles was normal. The poison appeared to have a powerful hæmolytic action on the red blood cells with which it came in contact and the hæmorrhagic areas in the arms were most marked along the course of the lymphatics along which the poison would be carried up the limb.

Mercurochrome—sodium dibromoxymercuryfluorescein—has been extensively used in the treatment of obscure septicæmic condition. J. H. Burn[32] has shown that samples from different manufacturers vary greatly as regards toxicity. Some samples were three times as toxic as others. This drug while acting more especially on the kidneys and colon must also have a toxic action on the liver and give rise to the risk of toxic jaundice.

Acriflavine.—E. R. Cullinan[33] has called attention to the occurrence of toxic jaundice after the administration of acriflavine. He quotes a case where, after the oral administration of gr. ½ 4-hourly for two months, jaundice developed. Death occurred 14 days later from acute necrosis of the liver. He referred to the experience of Major D. H. Murray who found in 118 cases to which intravenous injections of acriflavine had been given, 11 per cent. developed jaundice. One of these cases died from acute hepatic necrosis. In 1925 Meleney and Zau[34] showed that 0·025 g. per kg. of acriflavine of body-weight killed rabbits in six days. Acute degenerative lesions of the liver and kidneys were found after death. Cullinan's conclusion was that with acriflavine or its derivatives, whether given by the mouth or intravenously, there was a danger of producing toxic jaundice.

EFFECT OF
BRAIN DIET IN PERNICIOUS ANÆMIA.*

BY CHARLES C. UNGLEY, M.D. DURH., M.R.C.P. LOND.,
MEDICAL REGISTRAR, ROYAL VICTORIA INFIRMARY, NEWCASTLE-UPON-TYNE, AND MEDICAL TUTOR, DURHAM UNIVERSITY COLLEGE OF MEDICINE; ROCKEFELLER MEDICAL RESEARCH FELLOW.

SINCE Minot and Murphy[1–4] first demonstrated that liver contained material effective in pernicious anæmia, it has been found that other organs are potent in this disease. These investigators also found that kidney was effective, an observation which has been confirmed by McCann[5] and others. In a series of experiments, Castle[6–8] has shown that potent material arises after interaction of beef muscle with normal human gastric juice. On the basis of this work, and after confirming the observation in one case, Ungley[9] gave a diet of raw sheep's stomach to two patients with pernicious anæmia, with a resulting reticulocyte response; and Sturgis and Isaacs,[10 11] Conner,[12 13] and Wilkinson,[14 15] working independently, have clearly demonstrated the potency for pernicious anæmia of hog's stomach. The effectiveness of stomach tissue, however, does not necessarily indicate that the responsible factor is present during life; it is possible that its presence results from a post-mortem interaction between the intrinsic factor and the protein of the stomach wall.[8 10]

It would seem that the specific factor is synthesised in the gastro-intestinal tract, and that the liver, kidney, and possibly other organs act merely as storehouses.[8 9]

Although Minot and Murphy[1] noted neurological improvement in their cases, there has since been considerable difference of opinion amongst other observers as to the efficacy of liver and liver extract therapy with regard to the symptoms resulting from damage to the nervous system. The results obtained in the series of cases reported by Ungley and Suzman,[16] by Baker, Bordley, and Longcope,[17] and by Suzman,[18] as well as by other physicians,[19] show that whole liver in adequate amounts is effective in the majority of cases.

In analysing our results, Suzman and I stated: "It appears that the beneficial effect of liver on the nervous system is a specific phenomenon, and not the result of the maintenance of the red cell count at a high level, nor of improvement in the general condition."[16] So far as we are aware, there is no evidence at present that refined commercial extracts will produce similar neurological benefit, although it is possible that such effects might follow the prolonged administration of large amounts. As suggested formerly,[9] there is perhaps a factor which favourably affects the neurological phenomena separate from the one which influences the regeneration of blood. The existence of two such independent factors could be determined in several ways, one of which would be to treat a series of patients for a prolonged period of time with the crystalline compound isolated from liver by West and Howe,[20] which is at least very potent for blood regeneration. Such a procedure is not possible at present owing to the difficulty and cost of producing the substance. Another method of approaching the matter is presented below.

---

* From the Royal Victoria Infirmary, Newcastle-upon-Tyne.

The lesions in the nervous system are probably the result of a conditioned deficiency[16] just as is the anæmia.[8,21,22] Histological changes in the cord very similar to those in the subacute combined degeneration of pernicious anæmia may occur in pellagra, lathyrism, ergotism, beri-beri, and possibly sprue. Moreover, there is experimental evidence which tends to uphold this deficiency theory. Following Cowgill's original work,[23] Gildea, Kattwinkel, and Castle[24] have produced in dogs changes considered to resemble combined system disease in man by means of a diet deficient in the antineuritic vitamin B (B_1 or F). On the other hand, Mellanby[25,26] has observed cord degeneration similar to that in pernicious anæmia in dogs fed on a diet rich in cereal, but lacking vitamin A. Mellanby[26] discusses the possibility that the beneficial effects produced by whole liver in subacute combined degeneration may be due to the fat-soluble part of liver. In any event, it seems probable that the regression of neurological symptoms and signs which follows adequate liver therapy is the result, at least in part, of supplying sufficient quantities of a material that can favourably affect the damaged nervous tissue.

Knowing the degree of effect which liver produces upon the anæmia and upon the neurological phenomena, the ratio of these effects to each other may be used as a standard for comparison. Thus, if it were found that the ratio of the effect upon the nervous system to the effect upon the bone-marrow was markedly different following the administration of an organ other than liver, the existence of two separate factors could reasonably be inferred. It seemed logical to suppose that in nervous tissue one might find both factors, with perhaps a relatively large proportion of the substance beneficial to the neurological condition. For this reason experiments were commenced with a diet of brain.

Clinical Experiments.

The first step was to ascertain whether the blood-regenerative factor was present in brain; the second to determine the effectiveness or otherwise of brain in the treatment of the neurological phenomena.

Method.—Whole bullock's or sheep's brains were used in amounts of 240 to 480 g. (½ lb. to 1 lb.) daily. The material was obtained fresh daily as far as possible, minced, and fed raw. It has been found to be most palatable as a purée with orange juice, ginger ale, or broth, or as a jelly. Desiccated brain (Oxo Ltd.) was administered in three cases, two of which are reported here. In the third, its use was discontinued after a few days because of bowel disturbances and diarrhœa.

As a rule the brain was taken without difficulty. No liver, liver extracts, nor any other known potent material was given during the period of administration of brain.

The results obtained in four cases of pernicious anæmia and in three cases of simple achlorhydric anæmia will now be described.

CASE RECORDS.

CASE 1.—A widow, aged 44, entered hospital with typical pernicious anæmia. The duration of symptoms referable to anæmia was 20 months. For six months there had been weakness of the legs and paræsthesiæ of the extremities. Numbness and tingling involved the fingers and the lower limbs as far up as the knees. She had not had liver therapy at any time. Neurological examination showed some impairment of coördination of the lower limbs without evidence of pyramidal tract involvement.

Following the daily administration of 240 g. of ox brain there occurred the hæmopoietic response illustrated in Fig. 1. Subjective improvement was noticeable by the third week. At the end of 58 days numbness and tingling had disappeared except in the ends of the toes.

An attempt was made to raise the red cell count to five million with brain alone. However, after leaving the hospital, the patient had difficulty in obtaining enough of the substance, and supplemented it with liver. From the Chart (Fig. 1) it will be observed that the red cells increased more rapidly with this diet, which consisted of two pounds of liver and one half-pound of brain a week.

CASE 2.—Male, aged 47, had pernicious anæmia and subacute combined degeneration of 15 months' duration. Numbness and tingling involved the distal one-third of the fingers and the soles of the feet. His gait was slightly ataxic and neurological examination showed considerable involvement of both lateral and posterior columns of the spinal cord.

Before commencing brain diet, it was decided to observe the effect, if any, of vitamin B on the neurological condition in view of the work[23,24] already mentioned. Vitamin B was given in the form of detoxicated embryo of wheat, (Bemax) in doses of 270 g. daily. During this period there occurred an increase of reticulocytes, of mature red cells, and of hæmoglobin, to be discussed further on (Fig. 2).

There was some increased sense of well-being, though less than that which occurs with liver therapy. Paræsthesiæ were unaffected and there was no significant neurological change.

Desiccated brain (Oxo Ltd.) was now commenced in doses of 3·2 oz. daily. This amount is that derived from 1 lb. (480 g.) of whole ox brain. A small reticulocyte response followed, but at the end of 17 days the red cell level was practically unaltered (Fig. 2). The preparation was then discontinued owing to intestinal colic and diarrhœa. Numbness and tingling showed some improvement in degree, but no decrease in extent.

There was no special alteration of the neurological condition during the short period of desiccated brain therapy. Subjective improvement in well-being occurred after 10 or 11 days, but disappeared with the onset of bowel disturbances. The subsequent hæmopoietic response to liver is depicted in Fig. 2.

CASE 3.—A single woman, aged 39, entered hospital suffering from pernicious anæmia and advanced subacute combined degeneration. The disease commenced two years previously with soreness of the tongue and symptoms referable to anæmia. Numbness and tingling of the lower limbs up to the hips began soon afterwards. Ataxia, weakness, and stiffness of the legs developed and became progressively worse. Liver was taken infrequently and in inadequate amounts. For the past three months she had been bedridden, and unable to stand or walk.

Generalised bronchitis with œdema at the bases of the lungs was present on admission. She was markedly pale. Both upper and lower limbs showed evidence of gross pyramidal involvement. Coördination and joint sense were considerably impaired in the legs, with absence of vibration sense below the knees.

The increase of reticulocytes during the period of administration of desiccated brain is shown in Fig. 3. The preparation was discontinued after 12 days because of vomiting. No subjective improvement occurred, nor was there any significant increase of red cells during this period. The subsequent administration of extract (Liveroid) derived from 360 g. of whole liver produced a satisfactory hæmopoietic response (Fig. 3).

CASE 4.—A widow, aged 47, had pernicious anæmia with spinal cord symptoms. The onset was sudden, 16 weeks before entry. Neurological examination showed evidence of pyramidal and posterior column involvement affecting both upper and lower limbs. Her gait was grossly ataxic.

The effect of brain diet upon blood regeneration is illustrated in Fig. 4. Slight subjective improvement in the legs was noted after the tenth day. Liver therapy was substituted at the end of 18 days. On the second day the legs became weaker. Acute fibrinous pleurisy developed on the tenth day, and acute phlebitis of the left femoral vein ten days later. Retention of urine followed, and the urine became loaded with pus. These complications were accompanied by considerable fever and leucocytosis, and ended fatally.

Necropsy showed thrombosis of both femoral veins, extending to the inferior vena cava, and occlusion of the right pulmonary artery with clot, possibly embolic in origin. The spinal cord was the seat of subacute combined degeneration. Microscopically there was in addition to degeneration of the myelin some increase of glial cells and of fibrous glia.†

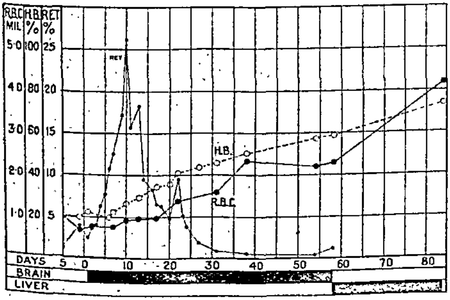
CASE 5.—A married woman, aged 30, suffered from "secondary" anæmia of three years' duration. There was no history of hæmorrhage and no apparent cause for the anæmia apart from a complete achlorhydria. The tongue was pale and clean with atrophy of the papillæ around the edges. The spleen was easily palpable on inspiration. Neurological examination was negative.

Blood examination showed an anæmia of "secondary" type, with marked achromia and moderate anisocytosis and poikilocytosis. The average diameter of the red cells was 6·6 μ (median), with 1·5 μ (dispersion).‡

The effect of brain diet is illustrated in Fig. 5. There was some subjective improvement after the eight days. From the twentieth day onwards the patient failed to take full amounts of the brain owing to gastric symptoms.

CASE 6.—A married woman, aged 39, gave a history of anæmia of three years' duration. Symptoms included sore tongue, slight dysphagia, and numbness of the hands and feet. An atrophic glossitis was present, and there was complete achlorhydria. The spleen was not palpable. Blood examination showed an anæmia of "secondary" type with 2·43 million red cells and 40 per cent. hæmoglobin (Sahli-Leitz); the erythrocytes were somewhat achromic with moderate anisocytosis and poikilocytosis, platelets numerous. The average red cell diameter was 7·5 μ (median) with 1·5 μ (dispersion).

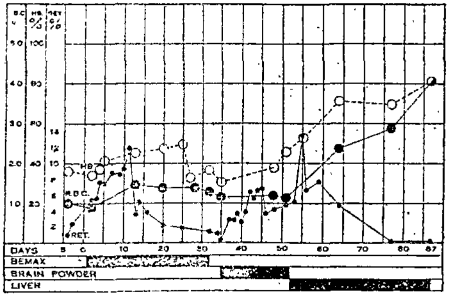
FIG. 1 (Case 1).



Pernicious anæmia. Effect upon reticulocytes, red blood cells, and hæmoglobin of feeding daily 240 g. of raw brain. In this and the following charts, Ret. = percentage of reticulocytes, Hb. = hæmoglobin percentage (Sahli-Leitz), R.B.C. = red blood cells per c.mm., in millions.

The administration of 240 g. of brain daily for a period of 20 days produced no significant alteration of the blood picture. Numbness and tingling of the extremities disappeared, however.

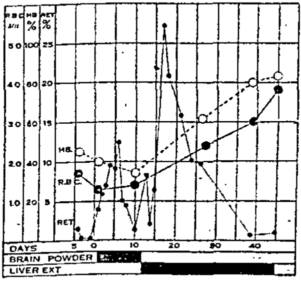
FIG. 2 (Case 2).



Pernicious anæmia, showing: (a) Increase of reticulocytes to 11·8 per cent. during the administration of detoxicated embryo of wheat, 270 g. daily. Initial red cell count 1·02 millions per. c.mm. with 36 per cent. hæmoglobin. Rise of red cells to 1·4 million per c.mm. and to 48 per cent. hæmoglobin in 20 days. Subsequent fall of hæmoglobin following diarrhœa of several days' duration. (b) Second reticulocyte response of 6·8 per cent. on the eleventh day from desiccated brain derived from 480 g. of fresh tissue. No significant increase of red cells in 17 days above the initial count of 1·15 millions per c.mm. (c) Tertiary reticulocyte response of 13·4 per cent. on the fourth day after feeding daily 240 g. of liver with extract (Liveroid) derived from a similar amount. Rapid increase of red cells and hæmoglobin.

CASE 7.—A widow, aged 30, gave a history of anæmia following severe menstrual hæmorrhage a month previously. There was no glossitis and no history of sore tongue or paræsthesiæ. The spleen was just palpable. Gastric analysis after histamine showed complete absence of free hydrochloric acid and pepsin. The erythrocytes which numbered 2·16 million per c.mm. with 30 per cent. hæmoglobin, showed marked anisocytosis, poikilocytosis, and some achromia. The average diameter of the red cells was 7·0 μ (median) with 1·5 μ (dispersion).

FIG. 3 (Case 3).



Pernicious anæmia showing: (a) Rise of reticulocytes to 12·4 per cent. on the sixth day during the administration of desiccated brain derived from 480 g. of fresh substance. (b) Secondary reticulocyte response to 27·2 per cent. on the fifth day, with rapid increase of red cells and hæmoglobin due to extract (Liveroid) derived from 360 g. of whole liver.

Ox brain, 240 g. daily, was given for 20 days without any hæmopoietic response.

Comment.

Although not directly concerned with the subject of this article, it is interesting to note the hæmopoietic response in Case 2 during the administration of detoxicated wheat embryo. The observation needs confirmation before conclusions can be drawn. The reticulocytes were already rising when the vitamin B preparation was first given, so that the possibility of a spontaneous remission cannot be excluded. Minot and Murphy[2] have reported a case of pernicious anæmia in which the administration of extract of wheat embryo produced no demonstrable effect.

---

† Although such glial increase is exceptional in an untreated case, Davison[11] states that it is the usual finding in patients who have had liver therapy.

‡ As measured by ocular micrometer, and using a stained smear mounted in balsam. By this method the normal median is 7·8 μ to 7·9 μ with a dispersion of 1·0 μ.[11]

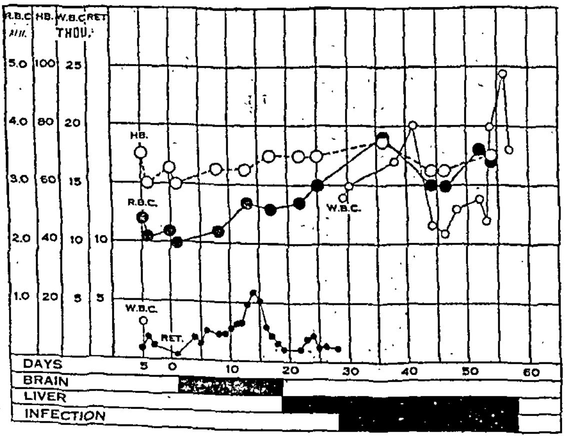
Discussion.

From the results obtained in the four cases of pernicious anæmia described above, it appears that brain contains a substance effective for blood regeneration in this disease. By comparing the reticulocyte response and the rate of red cell increase with those which follow liver in similar amounts,[3 4] one may estimate the hæmopoietic potency of brain relative to that of liver.

Thus in Case 1, the expected reticulocyte rise from 240 g. of whole liver, with an initial red cell count of 770,000 per c.mm. is about 40 per cent. The calculated amount of liver required to give the obtained reticulocyte response of about 20 per cent. is roughly 130 g. The increase of red cells is less than could be expected in 30 days from 240 g. of liver—i.e., 0·9 as against 2·0 millions. The estimated quantity of liver which would give an increase of 0·9 million in 30 days is about 120 g.

The reticulocyte rise which occurred in Case 2 following powder derived from 480 g. of fresh brain was only 6·8 per cent. compared to the rise of 40 per cent. to be expected from 480 g. of whole liver at a similar red cell level. The estimated amount of liver which would give a reticulocyte response of 6·8 per cent. at the same red cell level is roughly 80 g. It is possible that some of the effective substance in brain was lost during the process of desiccation. The rapid rise of red cells with a tertiary peak of reticulocytes, which followed an equivalent amount of liver and liver extract, indicate in the latter a much greater potency for blood regeneration.

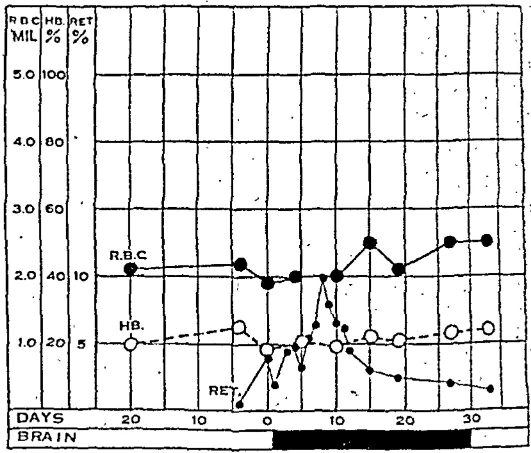
FIG. 4 (Case 4).



Pernicious anæmia showing: (*a*) Reticulocyte response of 5·9 per cent. on the fourteenth day of brain diet. The initial dose of 240 g. was increased to 480 g. on the fourth day. In 18 days the red cell count increased from 2·03 millions to 2·61 millions per c.mm. and the hæmoglobin from 60 per cent. to 70 per cent. (Sahli-Leitz). (*b*) Small secondary rise of reticulocytes to 2·1 per cent. on the sixth day from raw liver 240 g. (increased to 480 g. after six days) and liver extract No. 343 (N.N.R.) derived from 300 g. daily. The case was complicated by infection with accompanying fever and leucocytosis (W.B.C. = white blood cells in thousands.)

In Case 3 desiccated brain was also used. The expected reticulocyte rise from 480 g. of whole liver at a red cell level of 1·27 millions per c.mm. is about 35 per cent.; the amount of liver which would be required to produce the obtained reticulocyte response of about 12 per cent. at the same red cell level is approximately 140 g.

FIG. 5 (Case 5).



Simple achlorhydric anæmia: Reticulocyte response to 9·8 per cent. on the eighth day following 240 g. of raw ox brain daily. Rise of red cells from 1·89 to 2·5 millions per c.mm. but no increase of hæmoglobin.

In evaluating the reticulocyte responses in Case 4, it is necessary to make allowance for the presence of sepsis. Although the response to brain was small and delayed until the fourteenth day, the subsequent secondary rise with liver therapy was also small and less than would be expected. The estimated amount of liver required to produce a reticulocyte response of 5·9 per cent. at a red cell level of 2 million per c.mm. is 120 g., which amount would also be enough to give the rise of 0·6 million red cells per c.mm. obtained in 18 days with brain.

Taking these four cases together, and allowing for certain factors already mentioned, one may estimate the hæmopoietic potency of ox brain in pernicious anæmia as approximately one-third that of ox liver.

The effect of brain on blood regeneration in simple achlorhydric anæmia was mildly positive in one case and negative in two others. It is interesting to note that in Case 5 the red cell count rose without any increase of hæmoglobin. Similar dissociation of response may occur when cases of this type are treated with liver extract; the hæmoglobin percentage may fail to rise until iron is substituted or added.[18]

It now remains to assess the value of brain feeding in subacute combined degeneration of the cord. Whereas for the determination of hæmopoietic potency there is a rapid measurable response it is much more difficult to estimate the effect of a therapeutic agent upon the neurological condition; the rate and degree of improvement are variable even in cases apparently similar and receiving identical treatment. The cases reported above give no positive information as to the effect of brain on the nervous system because the periods of observation were too short. The results so far obtained in a further group of patients with subacute combined degeneration of the cord suggest that its efficacy in this respect is perhaps as great as, and possibly greater than, that of liver. However, it will take many months before it is possible to evaluate satisfactorily the potency of brain in the treatment of the neurological condition.

I wish to express my thanks to the members of the honorary staff of the Royal Victoria Infirmary, Newcastle-upon-Tyne, England, and particularly to Dr. George Hall and Dr. J. C. Spence, for the facilities they afforded me in this work. I am indebted also to Dr. M. M. Suzman, who kindly carried out at the Massachusetts General Hospital the investigations in Case 2, and to Dr. J. H. Means for permission to publish that case.

EOSINOPHILIA.

A RECORD OF THREE CASES.

By H. H. Sanguinetti, M.D. Oxf.,

PATHOLOGIST AND BACTERIOLOGIST TO THE LONDON TEMPERANCE HOSPITAL.

Except as a possible indication of the presence of intestinal parasites, very little attention is paid by the clinician to the percentage of eosinophil cells in the differential count of the leucocytes. An eosinophilia usually leads to a request for a search for parasites or their ova in the patient's stools, while an eosinopenia evokes no comment. This is not surprising, seeing that so little is known of the function of the eosinophil leucocytes. It has to be admitted that in many cases showing eosinophilia there is no explanation of the condition. In spite of frequent search for intestinal parasites or their ova, these have seldom been found in the cases examined at the London Temperance Hospital in recent years. Indeed, I can recall only one case where an eosinophilia of 11 per cent. in a youth led to the search for and discovery of parasites.

Of the ten cases shown in the Table the first five are probably examples of post-infective eosinophilia, which was accompanied by an increase of the lymphocytes and monocytes. The sixth case may have the same explanation, as the insertion of a foreign body—a piece of wood—would give rise to bacterial infection. Case 7 was possibly a reaction to protein poison from the disintegrating growth, while in Case 10 there may have been intestinal worms, which were not discovered in the laboratory. The first five cases indicate the prognostic importance of an eosinophilia, even if for diagnosis it proves of little value.

Table showing cases of Eosinophilia at the London Temperance Hospital, 1927–29.

Case.	Age.	Disease.	Number of leucocytes.	Percentage of eosinophil cells.
1	7	Empyema.	8,800	7
2	42	Gastric ulcer.	7,400	8
3	55	„ „	5,600	9
4	13	Subacute appendicitis	7,000	7
5	25	Rectal fistula.	10,200	17
6	51	Foreign body in rectum	7,600	8
7	35	Recurrent uterine carcinoma.	18,000	17
8	34	Abdominal lymphosarcoma.	7,000	6
9	24	Cirrhosis of liver.	14,400	8
10	20	Abdominal pain, history of worms, no ova found.	13,500	8·5

During the same period in which the cases in the Table were observed, three cases of marked eosinophilia were seen.

Case 1.—A railway-guard, aged 43, was first seen in the out-patient department on April 9th, 1926, and was admitted on April 18th, having a large painless swelling, due to enlarged lymphatic glands, occupying the upper part of the right anterior triangle and extending from just below the jaw to about 1½ in. above the clavicle. The swelling had first been noticed three months previously and had gradually enlarged and pushed the larynx 1 in. to the left of the mid-line. No enlarged glands were detected in the mediastinum or elsewhere, and the Wassermann reaction was negative. The patient suffered from a "rheumatic rash" on his body every spring, a dense papular rash being present on his loins and abdomen on admission.

Section of a gland removed from the neck had the appearance of lymphosarcoma rather than lymphadenoma but the diagnosis was doubtful. Treated with X rays the swelling ultimately disappeared completely.

The following were the results of the blood counts. April 9th: hæmoglobin, 9 per cent.; red cells, 4,520,000; white cells, 30,100; polymorphs, 28 per cent.; eosinophils, 48 per cent.; lymphocytes, 24 per cent.

April 19th: leucocytes, 9650; polymorphs, 48 per cent.; eosinophils, 20 per cent.; basophils, 3 per cent.; lymphocytes, 26 per cent.; large mononuclears, 3 per cent.

On April 30th the leucocytes had risen to 13,600 and the eosinophils to 41 per cent., falling again by May 5th to 12,000 with 14 per cent. of eosinophils.

The eosinophilia appeared to be associated with the skin eruption and disappeared when this subsided, some considerable time before the disappearance of the swelling in the neck. The patient entered the hospital again about a year later for an appendicectomy. No glandular swelling was detected at this time, but he died from a painful affection two years after he was first seen. Whether this affection was of the same nature as the original swelling has not been ascertained.

Case 2.—A single woman, aged 25, a hospital nurse, was admitted on March 21st, 1928. She had first noticed a lump in the left posterior triangle of the neck eight months before. For two months there had been a lump on the right side of the neck, and for two weeks a swelling in the left groin. She had lost weight during the last two or three months. Her mother and an aunt had died of consumption. Her brother and sister were alive and well.

She was a well-nourished woman weighing 7 st. 1½ lb. There was a large mass of smooth adherent glands the size of an orange in the right posterior triangle. No axillary glands were felt, but there was a small smooth gland above Poupart's ligament on the left side. Enlarged glands were felt deeper down in the left iliac fossa. The tonsils were not enlarged. There was an impaired percussion note over the manubrium sterni with weak breath sounds on the left side. There was no enlargement of the liver and the spleen was not felt.

The temperature was normal and remained approximately so until three weeks later, when a gland was removed from the neck for examination, after which the temperature rose to 100°–101° for 48 hours, and then fell to about 99° again. Six weeks after admission there was remittent fever for 17 days rising to 102°–103°, and then for a week the fever was intermittent.

Examination of the gland removed revealed the picture of lymphadenoma—namely, increase of endothelial cells, with many giant cells with centrally placed nuclei and hypertrophy of the reticulum. Many eosinophil leucocytes could be seen. No tubercle bacilli were found in the sputum and no parasites or their ova in the stools. The Wassermann reaction was negative.

On March 22nd a blood count revealed a hæmoglobin percentage of 80; 4,470,000 red cells, and 33,700 white cells; polymorphs, 30 per cent.; eosinophils, 61 per cent.; basophils, 1 per cent.; lymphocytes, 3 per cent.; and large mononuclears, 5 per cent.

On April 4th the hæmoglobin was 80 per cent., the red cells 4,490,000, and the white cells 36,800, with polymorphs, 11·5 per cent.; eosinophils, 77·5 per cent.; basophils, 0·5 per cent.; lymphocytes, 8 per cent.; and large mononuclears, 2·5 per cent.

On May 2nd the hæmoglobin was 62 per cent., the red cells 3,730,000, and the white cells 37,800; with polymorphs, 8 per cent.; eosinophils, 84 per cent.; lymphocytes, 7 per cent.; and large mononuclears, 1 per cent.

On May 11th the white cell count was 56,000; the polymorphs, 12·5 per cent.; eosinophils, 84·5 per cent.; lymphocytes, 2·5 per cent.; and large mononuclears, 0·5 per cent.

On May 17th the white cell count was 106,800, with polymorphs, 27 per cent.; eosinophils, 67·5 per cent.; lymphocytes, 4·5 per cent.; large mononuclears, 1·5 per cent.

On May 25th the white cells numbered 84,600; with polymorphs, 7 per cent.; eosinophils, 88 per cent.; lymphocytes, 4 per cent.; and large mononuclears, 1 per cent.

The patient died two or three months after leaving hospital, which she did at her own request.

There was no obvious explanation of either the excessive leucocytosis or the marked eosinophilia. G. L. Gulland and A. Goodall [1] state that in Hodgkin's disease there is usually a slight leucocytosis due to an increase of the polymorphonuclear cells, rarely beyond 15,000, but record a case with 61,000. Of eosinophilia they say "occasionally there is eosinophilia of from 4–10 per cent., rarely more," while according to V. Schilling [2] eosinophilia is not regularly present, and when it occurs is only slight. Strisower reported [3] a case in which there were 43 per cent. of eosinophils in the blood. Piney maintains that "Eosinophilia of well-marked character is not very common, but may reach quite considerable figures; usually this occurs in company with well-marked leucocytosis."

CASE 3.—A married woman, aged 39, suffering from uterine fibroids, was admitted on Nov. 26th, 1927. She had suffered from anæmia for 20 years. Her present illness had begun six weeks previously. She looked very anæmic, with pale conjunctivæ, lips, and palate, and was very short of breath. No glandular enlargement was found, with the exception of two slightly enlarged cervical glands. The spleen extended 3 in. below the costal margin, and the liver 3¼ in. A test-meal revealed no free hydrochloric acid. The stool contained no occult blood, parasites, or ova. The Wassermann reaction was positive + +.

A blood count taken on Nov. 28th showed a colour-index of 0·5, and a hæmoglobin percentage of 15. The red cells numbered 1,500,000 and the white cells 4200, with polymorphs, 26 per cent.; eosinophils, 35 per cent.; basophils, 1 per cent.; lymphocytes, 35 per cent.; and large mononuclears, 3 per cent. Poikilocytosis was present.

The diagnosis made was severe secondary anæmia. After a course of novarsenobillon injections with treatment directed to the improvement of the anæmia, the following blood count was obtained on Feb. 14th, 1928: hæmoglobin, 65 per cent.; colour-index, 0·56; red cells, 5,770,000; white cells, 4200; polymorphs, 58 per cent.; eosinophils, 11 per cent.; lymphocytes, 31 per cent.; and large mononuclear, 2 per cent.

The anæmia in this case was no doubt due to the syphilitic infection.

That in its tertiary stage syphilis may cause a severe anæmia of the pernicious type is, perhaps, not sufficiently recognised. The eosinophilia is unusual, but A. Piney [4] refers to an eosinophilic congenital syphilitic anæmia, which is accompanied by great increase of eosinophils, and although it is not known whether the case here reported suffered from congenital syphilis—and there may, indeed, be little ground for such a supposition—careful investigation would probably bring to light other cases of anæmia in tertiary syphilis associated with eosinophilia.

The eosinophilia present in each of these three cases was of an exceptionally high degree. Thus the highest percentage of eosinophils in the Table appearing in V. Schilling's "The Blood Picture" is 19 per cent. in a case of eczema with a normal number of leucocytes and in a case of peritoneal carcinoma. In the second case above reported both the leucocytosis and the eosinophilia are almost unbelievably high, probably higher as regards the eosinophilia than has heretofore been recorded. In the photomicrograph of one of this patient's blood films ten of the eleven leucocytes present are certainly eosinophils, the eleventh is doubtful.

In conclusion, I desire to express my thanks to my colleagues at the London Temperance Hospital, Dr. Kevin Byrne and Mr. James McClure for permission to use the notes of these cases under their care.

PSYCHOSIS IN OSTEITIS DEFORMANS.

BY STANLEY J. HARTFALL, B.SC., M.D. LEEDS,
M.R.C.P. LOND.,
MEDICAL REGISTRAR AND TUTOR IN THE UNIVERSITY OF LEEDS
LATE RESIDENT MEDICAL OFFICER, THE GENERAL
INFIRMARY, LEEDS.

THE absence of mental symptoms in osteitis deformans has been commented upon since the classical description by Sir James Paget [1] in 1876. It is well known that in this disease the skull bones are involved with great frequency, and extensive alterations are produced both in the external configuration of the head and in the capacity and shape of the vault. These cranial deformities have been investigated in detail and classified by Léri,[2] who has also drawn attention to the frequent narrowing of various foramina, both neural and vascular. Briefly, it may be stated that, apart from the greater thickness, there is an increase in the breadth of the interior of the skull while the antero-posterior diameter is lengthened. The depth of the cranial cavity, however, is diminished and the base of the skull becomes flattened or in extreme cases convex.

Despite these well-recognised changes affecting the skull and its foramina, symptoms due to cranial nerve involvement are uncommon. Wyllie [3] has commented on this and has reported two cases of osteitis deformans of the skull with optic atrophy due to compression of the nerve at the optic foramen. Gregg,[4] quoted by Wyllie, has reported compression of cranial nerves causing neuralgias, paralyses, and disturbances of the special senses. Mental symptoms are equally rare. Paget himself wrote: "Even when the skull is highly thickened and all its bones exceedingly altered in structure, the mind remains clear." Cases of altered mentality and of true psychosis have, however, been recorded by Hann,[5] in this country, and more recently in America by Smith[6] and by Kaufman.[7]

In Smith's first case a 50-years' inmate of an asylum was found to have developed Paget's disease but the two conditions were not ætiologically related. The second case, a female aged 60, was confused, delusional, hallucinated, and emotionally unstable, and this condition was thought to have a more direct relationship with Paget's disease and the arterio-sclerosis which accompanies it and which was present here to a marked degree.

Kaufman reported four cases, one of which was doubtful, being associated with a tumour of the cerebrum; the second, a female aged 53, developed psychotic symptoms of paranoid type at the age of 44 and later the changes of osteitis deformans were found in her skull and other bones; the third, a male aged 52, had gross neurological signs and a degenerative psychosis with similar bony disability; the fourth, a female aged 65 with typical Paget's disease of the skull, tibia, and femur, developed the simple deteriorating type of senile dementia.

Hann's case was one of osteitis deformans which showed mental deterioration during the last ten years of life. The bony condition was observed first in the right clavicle of the patient, a woman then aged 41. In ten years the condition advanced to affect obviously and in a classical way the legs, pelvis, arms, spine, and skull. Gross arterial degeneration was observed at this time and the patient began to complain of severe neuralgic pains in the limbs and intractable headache. Slowly, sight and hearing failed and mental symptoms made their appearance and progressed. At 63 cerebral apoplexy occurred; the patient was unconscious three weeks and then slowly recovered. Another such attack occurred at 65 and resulted in death. A partial post-mortem showed that the bony skull was thickened, soft, and reddish in colour. An unusual feature was the presence of numerous bony bosses projecting from the inner table of the vault and ranging from a walnut to a pea in size. Over them the dura was very adherent, and the grooves for the vessels deep. The brain and its vessels appeared normal to the naked eye. The vertex of this skull is preserved in the Museum of the Leeds Medical School and is figured in a text-book by Lawford Knaggs.[8]

In considering the clinical picture, which appears to be an early senile dementia, it is difficult to estimate how much mental deterioration can be related to the slow brain trauma of compression by the bony elevations on the one hand, and to cerebro-vascular degeneration on the other.

REPORT OF A CASE.

The patient was a male aged 63, a fitter by occupation. No familial neuropathic taint was discovered. He was admitted into the dermatological department of the Leeds General Infirmary under the care of Dr. J. T. Ingram. His complaint was of intense generalised itching; a feeling of pricking, especially over the scalp and face, and of "grit coming out of the eyebrows," and slight frontal headache of seven months' duration. His wife admitted that the patient had never been "quite right" and had not worked since the death of his only son four years before. He had developed very severe asthma at this time. Recently he had become a great trial to his friends and family doctor and on more than one occasion had threatened suicide. He had lost nearly 2 st. in weight.

The patient's appearance was somewhat striking; his head, especially the vertex, appeared large, and a superficial examination showed this to be due to bony elevations, particularly of his frontal and parietal bones. There was gross lichenification of the neck and scalp due to persistent rubbing, as a result of which the eyebrows had been entirely removed. Similar excoriations were present over the trunk, especially the shoulders, and a few on the thighs, and there were a few follicular scabbed papules of the scalp.

He described his symptoms intelligently. His attention was good, his memory fair, and his emotional state was on the depressed side. On being rather closely questioned, he elaborated a theory that the chronic irritation of his scalp was due to the presence of a fluid passing to and fro beneath it. He stated that these abnormal sensations, together with slight headache, had antedated the eruption by several months and had caused him to rub and scratch his scalp. He next developed the delusion that the lotions prescribed had got beneath the skin and left a sediment which felt like sand in a state of perpetual motion. He made little complaint of this, however, but was continually making furtive movements over the forehead and scalp which only served to perpetuate the chronic lichenification.

General examination showed a well-marked arcus senilis. The pupils were normal and the vision good. *Ophthalmologic* examination revealed retinal arterio-sclerosis. Hearing was normal, and the nervous system was otherwise normal. All the palpable vessels appeared to be thickened and degenerate. The pulse was regular. The systolic blood pressure was 155 and the diastolic 95. The heart, chest, and urine were normal. Radiological examination revealed Paget's disease affecting the skull-bones, pelvis, sacrum, and both femora. The blood and cerebro-spinal fluid Wassermann reactions were negative. The cerebro-spinal fluid was in other respects normal and the blood count was normal.

The patient continued with his delusion and developed several variants of it, but all with reference to abnormal sensations in the head and scalp.

INCIDENCE OF MENTAL CHANGES.

In order to investigate the frequency of mental changes a further 18 cases of Paget's disease of the skull, who had been in-patients at the Leeds General Infirmary during the past ten years, were investigated. None showed the slightest evidence of mental abnormality, nor were neurological signs suggesting compression of cranial nerves present, with one exception. This was a man who showed advanced disease of the skull-bones and had bilateral nerve deafness. Vision was good in all cases, and such minor changes as could be observed on ophthalmoscopic examination were not more than could be attributed to retinal arterio-sclerosis.

It is of interest to record that three cases in this series had developed sarcoma, one at the upper end of the left femur and a second over the right frontal eminence; the third, under the care of Dr. G. Watson, died of generalised sarcomatosis, the primary sarcomatous change occurring in the ileum with secondaries in the lungs and liver. Spontaneous fractures had occurred in four cases. In the case with sarcoma of the left femur a spontaneous fracture had occurred in the right femur three years before. A second case sustained a fracture of the upper third of the right tibia, the right humerus was affected in the third, while the fourth had a history of multiple fractures of long bones.

I am indebted to Dr. Ingram for permission to report this case and to the honorary physicians of the Leeds General Infirmary for allowing me to review their cases of osteitis deformans.

PITUITARY CYST.

AN ACCOUNT OF A CASE WITH TONIC FITS RESEMBLING TETANY.

By RANYARD WEST, M.D., M.R.C.P. LOND., D.P.H.,
PHYSICIAN WITH CHARGE OF OUT-PATIENTS, SEAMEN'S HOSPITAL, GREENWICH; MEDICAL REGISTRAR, HOSPITAL FOR EPILEPSY AND PARALYSIS, MAIDA VALE.

A CHILD of 5 years of age was taken suddenly ill one morning with frontal headache and vomiting. For two days he vomited all food given to him. He seemed drowsy, but complained of no abdominal pain, and there was no diarrhœa. Physical examination revealed nothing. The child was given alkalis and glucose. There was no acetonuria. There was a low fever. On the third day two convulsions were observed by the parents. The child was described as "drawing himself up and then going stiff all over." During the third and fourth days the vomiting continued whenever feeding by mouth was attempted, but not at other times. There was rapid wasting.

Physical Signs.—I examined the child on the fourth day of the illness. He lay on his side in an uneasy attitude. He had a hectic flush upon the cheeks. His eyes were sunken and his body wasted. Lethargy was marked, but he could be roused to obey simple directions, though he would not answer any questions. Nothing would persuade him to keep his eyes still for an instant, and ophthalmoscopic examination was thus impossible. There was fever of 100° F., but the pulse-rate was not raised throughout my visit. There was no sign of cranial nerve dysfunction, and no disease was found in the ear or throat. The tongue was thickly coated with a moist white fur. The muscles of the body generally were held a little stiffly; the neck resisted full flexion on the chest. Motor functions, as far as they could be tested, were found to be natural and equal on the two sides of the body. The reflexes were normal, with the exception that both knee-jerks were unduly brisk, considering the wasting of the muscles concerned. The left was exaggerated above the right. The plantar responses were flexor. No abnormality was found in the heart, lungs, or abdomen. The walls of the latter were "scaphoid" and resistant.

Course of Illness.—The patient was seen in the evening. A lumbar puncture was suggested, but this was not done, for the medical attendant found the boy very much improved on the following morning, the fifth day of the disease. Five days subsequently—on the ninth day—I was informed that the patient was sitting up and taking food well, and that he seemed nearly normal. Four days later I was again asked to see him. On the previous evening he had become unusually drowsy. Several indefinite fits had been noted by the parents, but none had occurred under medical observation. The doctor in charge had, however, found the child in an attitude characteristic of tetany, and this persisted until I made my second examination.

I found the patient lying limply on his back, unconscious. The head was not extended, but some rigidity was found on attempting movement. Both wrists were in rigid flexion; the hands were partly extended and the fingers strongly adducted, giving the hand the "obstetric" position. The feet were in the position of a performing toe-dancer, in rigid plantar-flexion. Rigidity of arms and legs was much less marked, but was obvious on attempting passive movements. The plantar reflex had now become extensor. No localising feature presented itself, but the father had noticed a squint lasting a short time and spasmodic movements of the left eyelid earlier in the day. The only other notable clinical feature was a continuous rolling nystagmus, without directional components, partaken of by both eyes. The temperature was 101° F. and the pulse-rate 100. The body was further wasted.

A differential diagnosis of tuberculous meningitis or deep-seated cerebral abscess was made, and a lumbar puncture agreed to. Immediately before this was undertaken three convulsions occurred, each lasting some 10 or 15 seconds. In each the trunk was slowly arched with the concavity backwards and to the right, the right leg stiffened into complete extensor rigidity, and simultaneously the left palpebral and facial muscles underwent rapid twitching contractions. Fluid withdrawn by lumbar puncture was clear and under considerable pressure. Analysis showed doubling (50 mg.) of the protein content. Five cells per c.mm. were seen—all mononuclear. The chlorides remained normal. The glucose was raised to 100 mg.

The patient died a few hours later.

Necropsy.—The ventricles of the brain were dilated to a moderate hydrocephalus. A cyst the size of a large grape lay on the under surface of the brain and filled the space behind the optic chiasma. It grew backwards and to the left, flattening the under surface of the mid-brain. The cyst was unilocular and when ruptured it left a smooth concave surface of brain tissue, uncovered apparently by membranes and flattened over an area of 1 in by 1 in. It appeared to grow either from the optic chiasma itself or from the pituitary body. The latter was harder than normal to the touch.

Microscopical examination was undertaken by Prof. G. Haswell Wilson, who gave the following report: "This is an epidermoid carcinoma of the type which might develop from the remains of the hypophyseal duct. It contains a number of cystic spaces, and in places the stroma contains islands of cartilage and spicules of bone. It is sometimes referred to as an "adamantinoma" of the pituitary. It appears to have destroyed the anterior part and to be invading the pars nervosa."

COMMENT.

The question of the differential diagnosis of the precise nature of the tumour is of interest. Its histology does not conform to that of the cysts of Rathke's cleft described by Worster-Drought, Carnegie Dickson, and Crowhurst Archer.[1] There is no ciliated epithelium and no cholesterol, nor is the cyst simple in type. The presence of cartilage and bone might suggest a teratoma. No highly organised tissues were present, however, and manifestations of metaplasia in adamantinoma have been recorded by Ewing.[2]

The entire destruction of the anterior portion of the pituitary body is of interest. In a child of 5 the manifestations of pituitary deficiency of a minor character are difficult to recognise. In the case of a cyst of Rathke's cleft, referred to above, however, reference is made to the child being backward in development before the age of 5. In a case of adamantinoma, recorded by Critchley and Ironside,[3] the child, at the age of 10, had the appearance of a delicate child of 6 or 7. One would expect a complete destruction of the anterior lobe of the pituitary body, such as is described in this case, to produce some signs of delay or alteration in fat metabolism and skeletal development. Doubt has been thrown upon the constant relationship of loss of the anterior lobe of the pituitary body and signs of infantilism. Difficulties arose in ascribing such divergent syndromes as that of Fröhlich and that of Lorain, to lesions of one and the same organ. Camus and Roussy[4] showed that symptoms of "dyspituitarism" could be produced by injury to the tuber cinereum, the pituitary body being left intact. On the other hand, Bellerby[5] quotes Paulesco,[6] Cushing,[7] Blair Bell,[8] and Smith[9] to the effect that removal of the anterior lobe produces a syndrome identical with that of dystrophia adiposogenitalis, and that the disability can be removed in some cases by grafts of portions of the gland. Blair Bell states that clamping or separation of the infundibular stalk was found more effective than removal of the gland in causing the lesions in question.

Critchley and Ironside analysed six cases of adamantinoma. Of these, four had persistent headaches and vomiting bouts over a long period. Ophthalmic signs or symptoms occurred in the majority. One had bitemporal hemianopia; one diplopia and failing vision, with paracentral scotoma and swelling of one optic disc. One had blurred vision with bilateral papillœdema. One had mistiness of vision, and in one consecutive optic atrophy was found. These authors refer to no change in the blood or cerebro-spinal fluid. Worster-Drought, in his case of Rathke's cyst, found a blood-sugar of 0·086 per cent. with a raised sugar-tolerance curve. My case had a cerebro-spinal fluid sugar content of 0·1 per cent.—a slight but definite rise above normality. A striking feature of Critchley and Ironside's series was marked alopecia in two cases.

An interesting and unexplained feature in my case was the occurrence of tonic muscular contractions simulating tetany. There was no reason to suspect true tetany, but calcium chloride with a small dose of Collip's parathyroid extract (5 units) was given. No change in the carpo-pedal spasm or in the general spasticity occurred during the remaining few hours of the child's life. Critchley and Ironside record a comparable occurrence of rigidity in one of their series. It was in a woman of 24 years of age, in whom a decompression operation had been performed for the relief of symptoms. In this case attacks of head retraction occurred, and these were followed by "extension and rigidity of the limbs, flushed face, and immobility of the respiratory muscles." The attack lasted from 15 to 20 seconds. The authors regard the phenomenon as one of decerebrate rigidity. True decerebrate rigidity is produced experimentally by section of the motor tracts, below the level of the red nucleus. The pyramidal and rubro-spinal tracts must be divided.

Cases of "tetany" occurring in cerebral tumours, cerebellar cysts, and syringomyelia are recorded.[10] Dr. James Collier allows me to mention an unpublished case of his at the National Hospital, Queen-square, in which fully developed tetany was associated with papillœdema and slight deafness. In this case a large eighth-nerve tumour was removed from the lateral recess, with resolution of the symptoms. Unilateral tetany has been recorded in syringobulbia,[11] and in cerebral hæmorrhage.[12] In both cases peripheral mechanical and electrical hyper-excitability were present. In Collier's case, as in mine, the diagnosis rests upon the clinical picture only, largely, that is to say, upon the posture. Collier has considered that some cases described as tonic basal epilepsy are in reality cases of tetany associated with a lesion of the central nervous system.[13] Whether electrical and mechanical hyper-excitability are to be regarded as essential features of tetany depends partly upon definitions and even more upon our further enlightenment as to its pathogeny. The method by which the pattern of tetany is imprinted is as yet obscure. But cases such as the one recorded serve as a reminder that the problem is a neurological as well as a biochemical one.

CLINICAL AND LABORATORY NOTES

A GLYCOSURIC FAMILY WITHOUT HYPERGLYCÆMIA.

SO-CALLED RENAL DIABETES.

BY F. PARKES WEBER, M.D. CAMB., F.R.C.P. LOND.,

SENIOR PHYSICIAN TO THE GERMAN HOSPITAL, LONDON.

THE MOTHER.

Mrs. E. B., an English woman, now aged 57 years, is known to have passed sugar in her urine (between 1 and 4 per cent.) for at least 44 years—without hyperglycæmia, polyuria, excessive thirst, or other distinguishing signs of diabetes mellitus. Owing to the absence of polyuria such cases cannot correctly be termed "*diabetes,*" *at least, not according to the* original meaning of the term. They can hardly even be termed "renal," excepting in the sense that the glycosuria is due to a low renal "threshold" for sugar, which is a congenital-developmental condition, as the history of the present family (and some other families) shows. Probably glycosuria till now has never been known to have existed quite so long as 44 years, but the patient is every day breaking her own record, and, from the nature of the condition, as now admitted, it is clear that in others it may last for an equally long or longer time. There is no evidence that it has exercised any injurious influence on the general health of Mrs. E. B., or that per se it ever does so in similar cases.

I first saw Mrs. E. B., on June 18th, 1914, when she was 40 years old, on her admission to the German Hospital under my care suffering from acute polyneuritis of uncertain causation; all four limbs were affected, *the upper ones much less severely* than the lower ones. In the hospital the paralysis began rapidly to disappear and by July 17th she could walk about a little. By July 30th her tendon reflexes had all returned.[1] The substance excreted was ordinary glucose, but there was neither polyuria nor excessive thirst, and the blood-sugar was found to be only 0·083–0·094 per cent. No disease in the thoracic or abdominal viscera was discovered by ordinary examination and the blood-serum gave a negative Wassermann reaction.

The most interesting point in the previous history of the patient was that in 1887, when about 13 years of age, she had been an in-patient at the Middlesex Hospital suffering from tonsillitis. From the medical registrar of that hospital I ascertained that according to the notes at that time (1887) she was passing 62 to 124 g. of glucose in 852 to 1705 c.cm. of urine daily, *the specific gravity of the urine being about* 1040.

In July, 1919, Mrs. E. B. saw Dr. W. Langdon Brown on account of headaches; he informed me that she still passed sugar in her urine and that her blood-sugar was within normal limits. When recently I saw her at the German Hospital on May 19th, 1931, her urine was of specific gravity 1036 and contained 3·5 per cent., sugar; it gave negative reactions for acetone and diacetic acid. The blood-sugar (fasting) was 0·096 per cent. There can therefore be scarcely a doubt that (as above stated) Mrs. E. B. has had continuous glycosuria since her urine was tested for the first time in 1887. She has lived a hard-working life and apart from fibrositic troubles and occasional headaches (possibly of the nature of migraine and sometimes accompanied by retching and, if she takes any food, by vomiting), her general health has been good.

In regard to Mrs. E. B.'s parents they are said to have been first cousins and to have died of pulmonary tuberculosis, aged 37 and 58 years respectively. I do not know whether either of them or both of them had glycosuria, but Mrs. E. B.'s two sisters and one brother have not glycosuria. However, Mrs. E. B.'s glycosuria ("renal diabetes") has been inherited by some of her children. She has had five children, all of whom are still living, and one miscarriage, in the following order.

THE FIVE CHILDREN.

1. A daughter, Mrs. P., aged 26 years, who is married and has one child, a boy aged 4 years. Specimens of urine from both of them, examined in May, 1931, have been found free from sugar. They have, therefore, probably escaped the familial glycosuria. It should be noted that this Mrs. P., the eldest child of Mrs. E. B., had a different father than Mrs. E. B.'s subsequent children have had, all of whom now have glycosuria without hyperglycæmia.

2. J. W. B., Mrs. E. B.'s eldest son, aged 21 years, a well-developed young man, when in New Zealand

---

[1] Weber, F. Parkes: Acute Polyneuritis in a patient with Chronic Diabetes Mellitus without Hyperglycæmia, St. Bartholomew's Hospital Reports, London, 1914, l., 163.

during November, 1930, complained of headache accompanied by a little vomiting, somewhat similar to his mother's attacks. His urine was examined and found to contain sugar. He was put on an anti-diabetic diet and treated with insulin till his return to England in May, 1931 ; in fact, he received insulin injections even during the voyage home. When I saw him on May 19th, soon after his return, he looked strong and sunburnt ; his urine contained 4·8 per cent. sugar and was free from acetone and diacetic acid. His blood-sugar (fasting) was 0·091 per cent. On May 22nd a blood-sugar curve was taken and found normal, the fasting blood-sugar on that occasion being 0·073 per cent.

3. A daughter, A. E. B., aged 20 years, whose urine, when tested recently, contained 4·3 per cent. sugar. Her blood-sugar curve (June 5th, 1931) was found to be normal, the fasting blood-sugar on that occasion being 0·089 per cent. She is well grown and the only obvious abnormality about her excepting the glycosuria is that she has a typical " nævus anæmicus " on her right hand, which I demonstrated on June 18th at the Dermatological Section of the Royal Society of Medicine. She sometimes has headaches similar to those of her mother.

4. A son, H. J. B., aged 18 years, had 0·3 per cent. sugar in his urine when it was tested recently. His blood-sugar curve on May 29th, 1931; was normal, but on that occasion his urine was free from sugar. It seems that he only occasionally has glycosuria. Dr. George Graham has referred to individuals with true " renal glycosuria," who pass sugar only after a meal. (A miscarriage at the fourth month came (in 1915) between this child and the youngest one.)

5. The youngest child, a boy, A. G. V. B., aged 15 years, was recently found to be passing urine containing 2·5 per cent. sugar. His blood-sugar curve, taken on June 5th, 1931, was normal, the fasting blood-sugar on that occasion being 0·084 per cent.

REMARKS.

This family group, though consisting of only two generations, is interesting, because it shows how in cases of the kind the glycosuria may increase the difficulties of diagnosis, when any infection or temporary illness occurs. Thus, in the mother, Mrs. E. B., in 1914, the unimportance of the glycosuria was not at first recognised when she was attacked by the alarming acute polyneuritis and was almost completely paralysed.

When her son (J. W. B.) had an attack of headache with slight vomiting, as his mother sometimes has, the discovery of sugar in his urine led (in a New Zealand hospital) to the diagnosis of grave diabetes mellitus ; he was apparently given to understand that he would fall a victim to diabetic coma if he did not keep to the special diet and continue the insulin injections. When I heard of his supposed dangerous illness, I naturally suspected that his glycosuria would turn out to be of the same nature as his mother's.

The case of the mother (Mrs. E. B.) is by itself of great interest, since it is clear that she must have been passing sugar in her urine for 44 years without being any the worse for it. Nevertheless, from the elaborate " Study of Orthoglycæmic Glycosuria with Particular Reference to its Hereditability," by Dr. Urban Hjärne (translated by Carl Westman, and published in Stockholm in 1927), a copy of which has been lent me by Dr. Graham, it appears that true diabetes mellitus may occur in " renal glycosuria " families. In the present family the fact that the parents of Mrs. E. B., were first cousins should be noted, though it is not known whether either of them had glycosuria.

I am indebted to the assistance of my house physician, Dr. M. Scholtz, and without the help of Dr. George Graham, I should not have been able to settle the nature of the glycosuria in Mrs. E. B. in 1914.

This account may prove of interest in regard to similar small family groups that are certain to turn up from time to time in England and abroad. Personally it may save me much trouble, as my printed accounts of rare or doubtful cases have sometimes done, by way of replying to doctors under whose observation the individuals themselves or members of their families subsequently fall.

RECOVERY FROM STREPTOCOCCAL SEPTICÆMIA

COMPLICATED BY BRONCHO-PNEUMONIA AND PERICARDITIS.

By A. H. G. Burton, M.D. Lond., D.P.H.,
MEDICAL OFFICER OF HEALTH, ILFORD ;
AND
A. R. Balmain, M.D. Lond., D.P.H.,
DEPUTY MEDICAL OFFICER OF HEALTH, ILFORD.

The high fatality-rate of streptococcal septicæmia is illustrated in the recent issue of *Guy's Hospital Reports*,[1] where, out of 21 cases recorded only six recovered. The treatment of the condition with serum appeared in this series of cases to be unsatisfactory, since out of eight cases which were treated with various brands of serum, seven ended fatally.

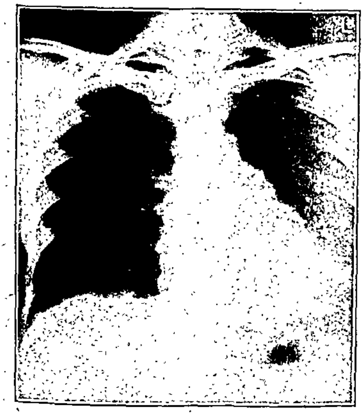
The authors of this section of the report state that there seems to be very little evidence in favour of the efficacy of serum therapy and emphasise the disadvantage of subsequent serum sickness. The occurrence, however, of serum sickness in patients treated with concentrated serum is of so little importance as to be negligible. We are inclined to think that the whole value of the treatment with serum depends on the specificity of the serum to the infecting organism. F. Griffith has described four types of scarlatinal hæmolytic streptococci, but as we have shown elsewhere [2] even in cases of scarlet fever over 53 per cent. of the types of hæmolytic streptococci found did not agglutinate with the four type sera. If, then, the serum with which the patient is treated is not specific for the infecting organism, no dramatic results can be anticipated, and if we are to regard the hæmolytic streptococci as in any way analogous to the pneumococcal and meningococcal types of organisms, the specificity of the serum administered is of the first importance. Good results have been obtained by the use of antiscarlatinal serum in the treatment of streptococcal septicæmia by Sanderson et al,[3] Burt-White,[4] Lord and Holmes,[5] Rosher,[6] and more recently by Comber.[7]

Cadham [8] claims remarkable success in the treatment of septicæmia ; out of 56 cases, of whom 38 showed a hæmolytic streptococcus in the blood, 45 recovered. He acknowledges the importance of specificity of the therapeutic serum and endeavours to obtain this by the use of multiplicity of strains of streptococci in the preparation of his immune sera. But he believes that, in addition to the use of specific sera, it is necessary to augment this treatment by the repeated transfusion of normal human serum in order to activate complement.

REPORT OF THE CASE.

The following case is of some interest because it shows that some sera will not benefit a case of septicæmia (although they are potent for certain strains of hæmolytic streptococci), while other sera will produce a dramatic cure. It is suggestive at least that the belief of Allison and Gunn [9] in the necessity of highly specific antistreptococcal sera for the treatment of streptococcal infections is well founded.

A probationer nurse at the Ilford Isolation Hospital, aged 23, was taken ill on Feb. 24th, 1930, with vague pains and pyrexia. She was at first thought to be suffering from influenza. She had a small subcutaneous abscess on the left thumb which was opened and yielded a growth of *Staphylococcus albus* and *Streptococcus viridans*. Although there was no evidence of hæmolytic streptococci in the pus, we think it was possible that the site of the abscess was the means of entrance of the organism. She, however, showed no signs of cellulitis, lymphangitis, or adenitis. The temperature was 103° F., but she showed no signs of being seriously ill. During the next day or two the pains of which she was complaining appeared to be more localised in the joints and the possibility of rheumatic fever was considered. On Feb. 29th, however, all her pain disappeared with the exception of that in her right knee which showed definite evidence of effusion into the joint. At the same time she developed pleurisy at the left base. A blood culture was taken and hæmolytic streptococci which were inagglutinable to Griffith's type sera were found.



Radiogram showing pericardial adhesion.

Her temperature which had been ranging from 103° to 101° came down to normal, but again rose on the sixth day of the disease. She was given 25 c.cm. of antipneumococcal serum and 70 c.cm. of antiscarlatinal serum (of a brand which we usually employ in our scarlet fever wards and which has given excellent results) during the next five days. Her condition gave rise to considerable anxiety; she was desperately ill with extreme cyanosis and marked dyspnœa. Oxygen was freely administered with Haldane's apparatus. The serum which had been administered had not the slightest effect upon her condition.

It should also be stated that the patient was treated from the beginning of the illness with vitamin A in the form of radiostoleum, but it had not the slightest effect on her condition. This confirms our previous views on this mode of treatment.[10]

In view of the fact that the hæmolytic streptococci which were found were inagglutinable we considered it possible that the serum which we had used was not specific for the toxin of the infecting organism, and on March 7th other intensive serum treatment was commenced. A total of 120 c.cm. of concentrated antipuerperal serum and 120 c.cm. of concentrated antiscarlatinal serum (of another brand than that administered in the first instance) were given from the 7th to the 10th. She developed well-marked pericardial friction at the base of the heart. The temperature came down to normal by lysis on March 12th and remained normal with the exception of two slight rises to 99° on March 24th and 27th.

The patient, however, showed signs of pneumonic consolidation of the lower half of the left lower lobe and also in the region of the right interlobar fissure behind, and this condition of the lungs remained stationary for a fortnight, in spite of the fact that the temperature remained normal except as stated above. This caused us to ask Dr. W. L. Yell, the Ilford tuberculosis officer, to see the case, since the possibility of pulmonary tuberculosis supervening seemed to be indicated. He, however, agreed with us that the condition was not tuberculous, and the sputum did not show the presence of tubercle bacilli. We therefore decided to desensitise the patient (this was done on March 29th) and to administer further doses of antitoxic serum. A further 68 c.cm. of antipuerperal serum and 70 c.cm. of antiscarlatinal serum were given. The general and local conditions now improved with remarkable rapidity, and signs in the chest of pneumonia and pericarditis gradually disappeared. By the 56th day the respiration-rate was normal and by the 65th day the pulse-rate had dropped to under 100. The patient made an uninterrupted recovery and was discharged on the 116th day of the disease. Three months later she returned to duty. She was then examined by ourselves and Dr. Yell who could find no signs of any lung disease with the exception of some restriction of movement at the left base. A radiogram showed that she has some adherence of the pericardium (see Figure). She has remained on duty at the hospital since and has done her work without any difficulty.[8]

On return to duty the patient was Dick tested and found to be Dick positive. It is also of interest to note that she was Dick positive on her entrance to the hospital and had been immunised.

COMMENT.

We think the following points are of interest in the case :—

(1) Difficulty of diagnosis : Ryle and Smith[1] have stated that there are four manifestations which may be regarded as diagnostic of streptococcal infection with a hæmolytic strain—namely, diarrhœa, albuminuria with red cells, rapidly progressing anæmia, and smooth red desquamating sore tongue. None of these was present in this case. The repeated rigors which are also considered of diagnostic importance and the enlargement of the spleen were also conspicuous by their absence.

(2) The importance of an early blood culture in cases of pyrexia of doubtful origin.

(3) The value of the treatment of streptococcal septicæmia with sufficient doses of concentrated antitoxic sera and the importance if one brand of antistreptococcal serum fails, of the recourse to another, our supposition being, as stated, that all antistreptococcal sera are not antitoxic to all types of hæmolytic streptococci.

(4) The ease with which such serum can be administered (in our case it was administered intramuscularly) and with which, in the event of complications developing, the patient can be desensitised and serum treatment again instituted with satisfactory results.

(5) With ordinary precautions the fear of serum sickness emphasised by Ryle and Smith is of no importance. This is the experience of observers who have been engaged in the treatment of scarlet fever with concentrated antiscarlatinal serum administered

hæmoglobin in the blood and the activity of the marrow as judged by the number of reticulocytes.—C. PRICE-JONES (London) found the normal average hæmoglobin of healthy young males in London to be 105 per cent. on the Haldane scale (with a range from 96–116), in Boston 112 per cent.; he suggested that the relative polycythæmia was due to mild chronic CO poisoning from motor engines. Women in London gave a mean of 98 with a range from 90 to 110.—R. MUIR (Glasgow) gave the result of his further investigation of Paget's disease of the nipple, which is undoubtedly due to the invasion of the epidermis about the nipple by malignant cells from a carcinoma arising in the ducts or acini.

I. BERENBLUM (Leeds) dealt in further detail with his discovery that mustard gas prevents the carcinogenic effect of tar; the influence is local and immediate, and not due to any effect of the gas on the tar.—D. F. CAPPELL (Dundee) described two unusual cases of what appeared to be adamantinoma of jaw, one of them with many foamy cells without lipoid.

L. R. W. PRICE (Glasgow) showed a rapidly growing carcinoma of the neck, believed to have arisen in a parathyroid rest or in the carotid body.—J. B. DUGUID (Cardiff) had a case of localised kidney atrophy due to tubular necrosis in a child of 4½ years.—W. A. ALEXANDER (Edinburgh) described the hæmorrhages into the rectus abdominis occurring in influenza. They occur always in the lower half of the muscle and are immediately due to violent coughing, though they are probably preceded by a change in the muscle analogous to Zenker's degeneration.—W. A. MACKEY (Edinburgh) found that in acute cholecystitis remnants of epithelium persist, from which a normal mucosa is regenerated.

DEMONSTRATIONS.

The following were also shown among the exhibits:—D. F. CAPPELL: three cases of primary carcinoma of jejunum, endosteal fibroma of fibula, leiomyosarcoma of skin. MAY H. CHRISTISON: colony variants of acid-fast and diphtheroid bacilli. S. McDONALD and R. J. WILLAN: tumours of testis. E. M. DUNLOP and H. E. MAITLAND: pleomorphic *Bacillus proteus*. J. KIRKPATRICK: methods of staining flagella. D. B. COLQUHOUN and J. KIRKPATRICK: motile typhoid glanders and plague bacilli isolated from apparently non-motile cultures. W. L. FORSYTH: *Bacterium dispar* of Andrewes. K. J. GUTHRIE: bacteriophage from sewage. J. W. S. BLACKLOCK: neuroblastoma; three tibias from the same child who twice regenerated a bone after osteomyelitis. T. RETTIE: a fresh method of staining fat with Nile blue. R. CRUICKSHANK: Zondek-Aschheim and Friedmann tests for the diagnosis of early and pathological pregnancy. G. L. MONTGOMERY: hypertrophic biliary cirrhosis. R. D. PASSEY: three spontaneous tumours in Plymouth Rocks. JANET S. F. NIVEN and R. ROBISON: calcification in vitro of embryonic rabbit bone. A. L. TAYLOR: malignant adrenal tumours; acromegaly; focal lesions in generalised vaccinia (post-vaccination death).

REVIEWS AND NOTICES OF BOOKS

Chronic Arthritis and Rheumatoid Affections.

With Recovery Record. By BERNARD LANGDON WYATT, M.D., F.A.C.P., Director, The Wyatt Clinic; Member Editorial Staff of "Acta Rheumatologica" of the International League against Rheumatism. Edinburgh: E. and S. Livingstone. 1931. Pp. 166.

So much has been published recently on the subject of arthritis and rheumatoid conditions that it is impossible for any book to contain entirely new material. But the reader interested in this disease will find Dr. Wyatt's book worthy of attention, since fresh aspects of chronic arthritis are discussed. An especially useful chapter is that devoted to joint exercises. The author gives his own methods and quotes at length from other authorities; he supplies adequate tables and offers some explanation of the value of the various movements. Another interesting section is that on climate and sunbaths. In the dry hot atmosphere of Arizona, where Dr. Wyatt is director of a sanatorium for rheumatic patients, chronic arthritis is practically non-existent amongst the residents. While sunbaths may be of great value n the treatment of chronic arthritis and fibrositis, the author condemns the indiscriminate use of solar therapy, which, in his experience, may be dangerous in certain cases. The arrangement of the material in the book is, we feel, not very well balanced. For example much space is allotted to the question of diet, which Dr. Wyatt acknowledges to be of minor importance, whereas such a fundamental section as physiotherapy is dealt with only in broad outline. The author considers his book suitable literature both for physician and patient. It is true that this is a disease where close coöperation between patient and physician is essential, but the wisdom of encouraging a patient to study a text-book on his own disease, especially when it is an intractable one, is open to question.

The book is easy to read and will provide useful information to doctors which they can pass on at their discretion. Those who find pleasure in apt sayings and quotations will reap here a rich harvest.

Treatment of Epilepsy.

By FRITZ B. TALBOT, M.D., Clinical Professor o Pediatrics, Harvard University Medical School Chief of Children's Medical Department, Mass chusetts General Hospital. London: Cassell an Company, Ltd. 1931. Pp. 308. 18*s*.

THE title of this book is misleading. It really consists of a brief account of epilepsy, and a full account of its treatment by the ketogenic diet. The author has divided the book into two separate sections, of which the second supplying valuable details of this particular treatment is discussed on p. 82 of this issue. In the first section an attempt is made to give some account of the history, incidence, ætiology, symptoms, pathology, diagnosis, prognosis, and treatment of epilepsy in 119 rather small pages. Reference is made to much of the recent work on epilepsy, and modern views on its ætiology are outlined and very briefly discussed, mostly on non-committal lines. Fortunately, this brevity is partly compensated for by an ample and admirable bibliography. But this section of the book is not nearly full enough for inclusion in a standard text-book of the disease; nor can it be placed beside other comprehensive résumés of modern work and views on epilepsy which have been produced in recent years. Nor is there much that is new in these 119 pages. Two points deserve attention here. First, the value of regular physical exercises, especially those designed to combat postural defects, is rightly stressed. Secondly, the author has travelled a long distance from the orthodox view of prohibiting marriage among epileptics. He holds that if the disease is individual rather than hereditary and the patient is able to contribute generously to the welfare of the community, there can be little objection to marriage with a healthy mate.

Even when the disease is hereditary the marriage would, in his view, be racially valuable rather than harmful if the other conditions were fulfilled, since not all the children would carry the epileptic taint, and the few abnormal offspring would not be a social burden. We cannot believe that many with an intimate acquaintance of the mental, physical, and social handicaps of epileptics would subscribe to these views.

Food Poisoning and Food-borne Infection.

By E. O. JORDAN, Chairman of the Department of Hygiene and Bacteriology, University of Chicago. Chicago: University of Chicago Press. Pp. 286. 11*s.* 6*d.*

PUBLISHED as one of the University of Chicago Science Series, this book succeeds in its aim of being accurate and scientific but not too technical. The title is used in a very wide sense, and covers subjects such as infectious disease spread by food and animal parasites, poisonous plants and animals, food allergy, metallic poisons in food, preservatives and colouring matters, milk sickness, ergotism, and lathyrism. The term "ptomaine poisoning," still frequently used, is condemned as inaccurate and unscientific. Interesting information is given on poisonous plants, some of which, such as rhubarb, are not commonly regarded as poisonous. A good account is given of mushroom poisoning. The subject of preservatives in food is discussed with common sense, and benzoic acid and the benzoates are regarded as preservatives for which a favourable case can be made out. In the United States their presence and amount must be plainly stated on the label. The author concludes: "We do not at present know what effect is produced in human beings of different ages and varying degrees of strength by the *long-continued* consumption of food preserved with particular chemicals." Excellent but comparatively short accounts are given of food poisoning from the Salmonella group and of botulism, the latter account being the more complete, no doubt in accordance with its particular importance in America. Between 1899 and 1927, according to Dr. Jordan, about 550 authentic cases of botulism in the United States were traced, and probably a considerable number were overlooked. In 1926 and 1927 there were only 6 and 11 cases respectively. An interesting account is included of toxic substances produced by certain staphylococci and streptococci which have been found associated with some outbreaks of food poisoning, much of the work having been done by Prof. Jordan or in association with him.

The volume may be recommended as a clear, accurate, and interesting volume on an important subject.

Die Primäre Verrücktheit.

Sammlung Psychiatrischer und Neurologischer Einzeldarstellungen. Vol. I. By KURT KOLLE. Leipzig: Georg Thieme. 1931. Pp. 268. M.25.

THE editors of the "Fortschritte der Neurologie Psychiatrie und ihrer grenzgebiete" could not have chosen a better work than this with which to start series of monographs. Paranoia is still one of the their most obscure subjects in psychiatry, and Dr. Kolle's painstaking investigation should do much to clear up some of the problems of this rare but important disorder. In pursuance of the modest aims stated in his preface, he has made a careful clinical. psychopathological, and genetic study of the Munich cases upon which Kraepelin based his conception of paranoia, and of others collected in the psychiatric clinic at Kiel. The work has occupied him almost exclusively since 1926, and its results are here set forth in detail so that the reader has available all the material for forming an independent judgment. Dr. Kolle's general conclusion is that these cases. judged by psychopathological and genetic criteria, represent a particular form of schizophrenia, to which he would apply Kraepelin's word "paraphrenia." His examination of the delusions, according to the method of the Heidelberg school, and his inquiry into family morbidity are well worth study by psychiatrists, as are also the admirable case-reports which comprise the second half of the work.

Vaccination préventive et curative du cobaye et du lapin contre la tuberculose humaine.

Ses indications et ses effets chez l'homme. By JULES AUCLAIR, Médecin de l'Hôpital temporaire du Bastion 29. Paris: Masson et Cie. Pp. 186. Fr.25.

La vaccination contre la tuberculose par le B C G.

By Dr. ROLAND CHAUSSINAND. Paris: G. Doin et Cie. 1931. Pp. 196. Fr.38.

THE basis of Dr. Jules Auclair's book is to be found in the employment of a special tubercle vaccine devised and prepared by himself. It consists of tubercle bacilli, either virulent or killed by heat, treated for several days with extract of the pancreas of the fowl at a low temperature. The details of the preparation of this vaccine as given here are extremely scanty; a little more information about it will be found in an article written by Dr. Auclair four years ago.[1] Several series of experiments with both types of vaccine in guinea-pigs and rabbits are described and the preventive and curative vaccination of these animals against *B. tuberculosis,* together with the use of tubercle vaccine in man, is discussed at some length. As a result of his experiments, Dr. Auclair concludes that guinea-pigs can be completely healed of tuberculosis by his vaccine, but if a weak dose of vaccine is used healing will take place only if the disease is but slightly advanced at the time of inoculation. Among rabbits the process of healing is said to take place more readily, and even in advanced cases. With regard to vaccination of man the author is cautious, stating that more prolonged clinical studies must be made before he can come to any definite conclusion; but he states that healing does take place in cases with external tuberculous lesions such as lupus, and cutaneous tuberculosis. In other cases, if vaccination takes place at the time of infection or soon after, Dr. Auclair believes that even if it does not always heal the lesions, at any rate it confers some degree of resistance and immunity for a long time. The book concludes with a very short bibliography.

Since Calmette first introduced his now well-known B C G vaccine there must have been little short of a thousand papers published of one kind and another dealing with the subject. Several collective reviews have been made in various journals, and now Dr. Chaussinand, evidently a disciple, epitomises practically all of the earlier work and many of the more recent papers. There is nothing new in the monograph. The conclusions reached by Calmette are clearly set out and a really excellent bibliography, probably the fullest that has yet been issued, is appended. We can recommend the book as a clear presentation of the claims of the Calmette vaccine, and the reader who makes use of it will be saved a vast deal of trouble in hunting up references to an enormous literature which has accumulated since Calmette's original paper was published in the Annales de l'Institut Pasteur in 1926. The reader who studies the book alongside the account given by Calmette himself in "L'infection bacillaire et la tuberculose," of which the third edition appeared in 1928 (Paris, Masson et Cie) will find himself possessed of practically all the information on the subject up to the beginning of 1930. The book contains a preface by Prof. Calmette.

---

Diagnosis and Treatment of Venereal Diseases.

Second edition. By David Lees, F.R.C.S., M.R.C.P. Ed., Surgeon in Charge of Venereal Diseases, Edinburgh Royal Infirmary. Edinburgh: E. and S. Livingstone. 1931. Pp. 634. 15*s.*

The second edition of Mr. Lees's book for students and practitioners is sure of a welcome, for it is not merely a text-book, but rather an exposition of the methods used in hospital practice and teaching by a practical man who is also an enthusiast about his subject. Modern methods of diagnosis and treatment of venereal diseases are clearly explained and where possible tabulated, so that the amount of treatment required for patients at any stage of syphilis can easily be grasped. A new chapter is supplied on cardiovascular syphilis, and the section on syphilis of the nervous system has been revised and supplemented.

The diagnosis and treatment of gonorrhœa are well described. It is of interest to note that Mr. Lees, in common with a good number of workers in venereal diseases, has been unable to obtain by local diathermy, either in males or in females, such good results as did Cumberbatch and Robinson, who strongly advocated this method.

A misprint or an omission in the first lines on p. 80 mars the otherwise admirable section on differential diagnosis of syphilis. The book contains 87 illustrations, over 70 of them being photographs of actual lesions. The colour photographs are particularly vivid.

This volume is a reliable and important addition to the bibliography of venereal disease.

A Text-book of Histology.

By Alexander A. Maximow, Late Professor of Anatomy, University of Chicago. Completed and edited by William Bloom, Assistant Professor of Anatomy at the University. London: W. B. Saunders Co., Ltd. 1930. Pp. 833. 40*s.*

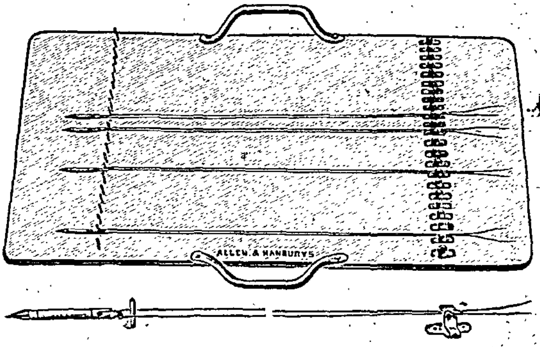
To general pathologists as well as to histologists the name of Maximow suggests original and erudite work. When he died in 1928, at the early age of 54, Maximow was writing a book of histology, and he had already progressed far with the work. He had completed the sections on the male and female generative organs, the urinary tract, the organs of special sense and epithelium, and he left in manuscript form the sections on the blood and connective tissue, the gastro-intestinal tract, the blood vascular and lymphatic systems, the spleen, the integument, and the mammary gland. Prof. Bloom, after Maximow's death, undertook the task of completing and editing the work. In this he was assisted by Prof. Herrick, who contributed much to the section on the nervous tissue, by Dr. N. Hoerr, who wrote the description of the suprarenal bodies, and by many others of Maximow's colleagues, including Prof. Bensley. Some assistance in the method of dealing with the various sections was moreover obtained from the 1918 Text-book of Histology in Russian. The final product is worthy of the name under which the book appears, and Prof. Bloom deserves gratitude for the way he has accomplished his task. Readers will naturally turn to the descriptions of the blood and connective tissue, since Prof. Maximow was an acknowledged authority on these subjects. They are clearly and convincingly written. No less sound in their teaching are the various parts of the book which have been written by the editor and his colleagues. The work is well illustrated and a few well-chosen key references to recent important works are inserted.

The book should take a leading place as work for reference and as a text-book for the advanced student.

NEW INVENTIONS

A TRAY FOR RADIUM NEEDLES.

The tray shown in the illustration, which has been made to my specification, has proved useful for carrying radium needles that are threaded prior to sterilisation. It is of metal, 15 inches long, and including the side handles, 12 inches broad; the angle at which the handles are placed enable it to be completely immersed in 1 inch of fluid. Each needle with its thread is held by a peg and a spring clip, of which there is a row of 24 near each end of the tray. The needles, after being threaded, are placed so that one of the double threads issuing from the eyes passes over each side of a peg; the threads are then pulled taut and fixed in the corresponding clips at the other end of the tray. The pegs and clips are placed so as to take threads of not less than 10 inches in length, but the tray can of course be made so as to accommodate needles with shorter threads. If the threads are knotted a little distance from the needles, it is simpler to draw the knots, rather than the eye ends of the needles, up against the pegs. The advantages of this tray are that on each one 24 needles can be carried, sterilised, and counted with ease and convenience, and with a minimum amount of handling. Entanglement of the threads is avoided, and only a very small depth of fluid is required for sterilisation—an important point if this is effected by immersion in spirit.



The tray has been made for me by Messrs. Allen and Hanburys, Ltd., Wigmore-street, London, W.

Edgar Freshman, F.R.C.S.

London Hospital.

THE LANCET.

LONDON: SATURDAY, JULY 11, 1931.

THE CENSUS OF 1931.

TEN years ago, in these columns, it was our pleasant duty to commend the Registrar-General for such prompt publication of the preliminary results of the thirteenth census. The record then established of a summary made public within three months of a collection of the returns has been beaten, for the preliminary results of the census of 1931 have appeared this week, while the returns were not available until the end of April. The total population enumerated at midnight on April 26th, 1931, amounts to 39,947,931 persons, the largest number hitherto recorded in the history of census-taking in this country, exceeding the numbers returned at the census of 1921 by 2,061,232 persons, and corresponding to an intercensal increase of 5·52 per cent. This percentage increase, however, with the sole exception of the increase noticeable for the decade 1911–1921, is only the half of any previously recorded. But the low rate of increase will come as no great surprise to students of the vital statistics of this country familiar with the substantial reduction year by year in the national birth-rate. The total births registered during the decennium 1921–1931 are no less than a million and a quarter fewer (or 16·3 per cent.) than the numbers recorded during the period 1911–1921—a period, it will be remembered, when the birth-rate declined to the lowest level ever recorded in this country. In this connexion the Registrar-General comments: "The full significance of the fall will be but dimly appreciated for many years to come; any temporary satisfaction felt in a reduction of the number of unproductive mouths to be filled during the present period of economic distress must sooner or later be qualified by a realisation of the profounder secular issues involved. The births of to-day govern the population of the future; and just as the nation which faced the upheaval of 1914 to 1918 was the product of the birth-rates prevailing towards the close of the last century, we are now observing the conditions which will shape the generations charged with the national destiny in the latter part of the present century." This unprecedented fall in the number of births during the decade is partially compensated for by the fact that, during the period under review, the numbers of deaths recorded were more than half a million fewer than those recorded during either of the two preceding decennia; in other words, allowance being made for the increasing age and numbers of the population exposed to risk, these figures represent a reduction in mortality of about 20 per cent. by comparison with the mortality figures for the decennium 1911–1921.

Turning to consideration of population variations in geographical sections of the country, in each of the regions selected for tabulation, with the single exception of South Wales, the population of 1931 in each section exceeds that recorded in 1921, the variations ranging from an increase of 10·5 per cent. in the South-Eastern Section, to a decrease of 3·6 per cent. in South Wales (Region W.1). It is significant to note that the areas associated with mining and the heavy manufacturing industries, which showed the largest population growths during the period 1911–1921, now find themselves, notwithstanding the higher birth-rates characteristic of these areas, relegated to the bottom of the list of increases of population during the decade 1921–1931. There are manifestly steady, though comparatively small, increases in the urban as compared with the rural elements of the population, though, in the opinion of the Registrar-General, "the latest record suggests almost that rural development is now materially in excess of urban." According to the preliminary figures, the population of the Administrative County of London has decreased by 2·0 per cent., while that of Greater London has increased by 9·7 per cent., and now totals 8,202,818 persons. The Registrar-General comments at length upon these changes, and is of the opinion that the London area is growing, not at the expense so much of rural areas as of the provincial towns, particularly those of South Wales and of the North of England. Of 1120 urban administrative areas, 113 had enumerated populations exceeding 50,000 in 1931, and these in the aggregate accounted for one-half of the total population of the country. Thirteen new areas find themselves included in the category of great towns. In the London area West Ham, East Ham, and Leyton all show decreases of population; the same is the case in Lancashire, in towns such as Barrow-in-Furness, Burnley, Salford, Wigan, Blackburn, Oldham, Bolton, and Rochdale; and in South Wales, in the Rhondda and Merthyr Tydfil; while seaside resorts like Eastbourne, Great Yarmouth, and Hastings show decreases of 7·4, 6·5, and 1·9 per cent. respectively.

The preliminary report concludes with brief reference to the ratios of males to females for the country as a whole and for individual areas. Here it is seen that sex distribution varies widely in different parts of the country—no novel feature, for relative positions of different areas have not been profoundly affected by any changes in proportions. The greatest preponderance of females is to be found in the South-Eastern Metropolitan region, while at the other end of the scale lies South Wales, where the males outnumber the females—though here it is to be remembered that the male excess is now lower than it was in 1921. The figures are, of course, provisional, but judging by past experience no material discrepancy is to be anticipated between those now before us and the results which will appear in the final census volumes. They provide a foretaste of the valuable data concerned with tracing the eddying tides of humanity which only a vast national stock-taking can provide.

THE FUNCTIONS OF A MEDICAL SOCIETY.

Dr. Raymond Crawfurd, in his opening address at the Harveian Society's centenary[1] stated that the functions of a medical society were, primarily, the diffusion of knowledge; as a necessary preliminary to that end the acquisition of existing knowledge, and (to a limited extent) the creation of new knowledge. Different societies, according to their particular constitutions and needs, perform these functions in different ways along different lines, the difference being chiefly in scale and method. We publish in the correspondence columns of this issue communications from three medical men who, from their interest in collective medical effort and the services that they have rendered to it, are exceptionally well qualified to speak on this subject. "A," in a comprehensive survey of existing medical societies, suggests a classification into three groups according to degree of specialisation, with hospital societies as a fourth group. He points out that the work of diffusing knowledge from the centre to the periphery is performed by meetings and discussions, by the publication of transactions, and by the maintenance of special library and translation services. He especially stresses the value of clinical meetings, asserting that the medical society affords to the practitioner a unique opportunity of securing advice on difficult cases, of enlarging his clinical knowledge and of developing his intellectual power by the difficult work of presenting cases. The general practitioner, he states, must possess a rich harvest of clinical material, and medical societies offer an easy and ready medium for the propagation of this knowledge. He observes rightly that one of the most promising roads of advance in medicine lies in the careful and accurate observation, annotation, and presentation of clinical work. He commends also the intimate friendly atmosphere of the small local society, a point which is taken up again by "C" in his insistence on the value of the collective expression of the views of local practitioners in any area. "B," on the other hand, emphasises the value of tradition, which he holds to be the chief element in the success of at least one hospital society. The traditional interest taken by students in the society ensures, he says, a much more active discussion by all ranks than is usually heard elsewhere. The meetings which are successful at other societies are, he writes, those at which some great contributor to medical knowledge (or his deputy) discusses his own work. Turning to a few small but very important details, he urges upon the executives of societies to ensure that foreign speakers are properly interpreted; that all speakers be made to speak up, and that all lecturers who illustrate their remarks should make sure that their illustrations are boldly set out and plainly visible at the back of the room. He points out that the value of a clinical evening can be much enhanced by the skilful selection of a small number of cases, so as to present a wide field of interest.

Dr. Crawfurd and our correspondents have between them left very little to be said about medical societies. It is perhaps arguable that they do not attach full weight to a factor which may be more important than anything else. Admittedly medical societies fulfil an indispensable work in propagating knowledge in printed form, whether it be in their own transactions or in books and periodicals. Nevertheless, in all the functions of a medical society the factor of personal contact is the one which supplies the dynamic. It is possible that a few research workers derive their creative inspiration from themselves or from one or two intimate contacts, but for most men the incentive to create, to collect, and to diffuse knowledge arises from the desire to serve, to strive with, and to emulate their fellows. A solitary job is to most men a hard discipline, an obligation rather than a pleasure. The member of a live medical society—and more so the member of two or more societies—feels that his job is not solitary; that he shares it with many others whose minds are like his own. Every member of a lively medical society has a real chance of attaining that invaluable prize, a life-long working friendship with one whose approach to life and medicine is absolutely congenial to his own. This consideration explains the importance of tradition, stressed by "B," for tradition is transmitted personal influence. It explains the intrinsic interest, also mentioned by "B," of a lecture by one of the great masters of the art and science of medicine. It explains the unique value of the clinical demonstration, and interprets more kindly than Dr. Crawfurd the attraction of the dinner meeting extolled by "A."

Moreover, it throws a sidelight on the rule of an old Gloucestershire Society, quoted by Dr. Crawfurd, that no new member should be admitted for seven years to come whose age exceeded 40—a rule with which Dr. Crawfurd hinted his sympathy and "B" expressed his profound concurrence. It is true that the official administration of societies tends to get far too much into the hands of the older members. Nevertheless, there are many men even under 40 whose appointment to office would not contribute greatly to the animation of a society, and many of advanced age whose deposition under such a rule would be an irreparable loss. Surely in the sphere of personal dynamism, as in that of the intellect, age is not measurable by years. Just as the "mental age" of many persons never exceeds 12 or 14 to the end of their days, so the social age of many valuable and venerable officers of medical societies remains always at a vigorous prime. The influence of the best, such as Hunter and Harvey, has survived to this day.

◆

SOCIAL PSYCHIATRY.

Those who try to educate the public in mental hygiene stress the high percentage of recoveries in mental hospitals and the importance of early treatment. They are also courageously working along many different lines to teach the far more difficult lesson that the only sound way to mental hygiene is preventive. This ideal will be stimulated by study of the Morison lectures for 1931.[1] Dr. D. K. HENDERSON argues with vigour and sound reason. His comprehensive essay contains much controversial matter but will bring encouragement and stimulation to all who read it, however much they disagree with some of the author's contentions.

---

[1] The Lancet, June 13th, p. 1275.

One of the points which will provoke discussion is the plea that mental hygiene should be placed on the same footing as physical hygiene, in line with the control of infectious diseases and the betterment of living conditions. To this end Dr. HENDERSON urges the centralisation of control in public health officials. He wishes to extend the term "public health" beyond its essentially physical meaning of to-day, to cover all means for preventing mental disease and defect. It is often argued that the aggregate recovery-rate in the mental hospitals of the country shows no appreciable tendency to rise, and that therefore psychiatry is making no progress. Even the Board of Control, he remarks, has expressed itself as disconcerted, and suggest that the reason lies in the more rigorous standard of recovery now demanded. In his view the reason is that, like all other hospitals, the mental hospitals are dealing with end-results, much damage having already been done. "We must get in at the beginning," he says; "medically, socially, economically, it is better to centralise on the recoverable than to care through a lifetime for those whose illness has been allowed to develop past all chance of betterment." Psychiatry he regards as a social and public health problem, to be debated in the clear light of day rather than behind the high walls of an institution. It needs the coöperation of all, medical and lay, who really have at heart the welfare of humanity, and unlike the study of tuberculosis or sanitation, psychiatry is intensely individual and personal and strikes at the liberty of the subject. This broad conception of psychiatry passes over in its first stride those who are already cared for in mental hospitals and institutions for the mentally deficient and concentrates attention on the socially inefficient, the unemployable, the epileptic, the habitual offender, the prostitute, and all others who have not been able to fit themselves harmoniously into the fabric of society. In the words of Dr. O. LEWIS, "the problem of mental inefficiency . . . must be one of the major social problems which a civilised community may be called upon to solve." Dr. HENDERSON insists vehemently that all forms of disordered conduct are due to inability to adapt; that institutions are very limited in their possibilities, and that a much more hopeful approach is to tackle those who have not yet developed any outspoken defect. Every case of disordered conduct must undergo an exhaustive examination to determine the relative importance of the various ætiological factors, hereditary and exogenous, and how they can be modified. He strongly condemns the fatalistic attitude of those who explain every aberration on an hereditary basis and abandon hope for the inefficient who has an alcoholic uncle or some relation who is a ne'er-do-well. He holds KRAEPELIN's view that heredity is a fact of experience, not a law which holds in every case. The avoidance of the propagation of defective stock, is, he protests, a matter for the individual conscience and not for legislation; the public should be educated to realise the tribulations which it brings to both parents and offspring. Rather than allow the sterilisation of defectives, he would strike at alcohol and venereal disease. He approves of our comparatively mild restrictive legislation on alcohol, but recognises that a greater factor in its control has been the higher standard of living and the more rational outlook which has grown up in this country. The public are understanding more and more clearly that alcoholism interferes with efficiency and brings distress, and public education must be directed to spread this knowledge. Venereal disease should, in his view, be combated along the same lines.

Dr. HENDERSON does not spare his colleagues. Side by side with efforts to educate the public and reconcile psychiatry with public activities, the profession must, he insists, put its own house in order and marshal its ranks more closely. Instead of maintaining an obscurantist attitude to psychiatry and keeping the psychiatrist in the background as an ogre with which to frighten recalcitrant patients, all ranks of the profession should make an effort to acquire a working knowledge of psychiatry. To this end he advocates the more comprehensive training of the medical student and closer coöperation between the general hospital and the more specialised departments of medicine. The student should be given a clearer idea of the normal and should be made familiar with the danger-signals and the early cases. Specialisation may prevent the conception of the patient as a whole by its over-emphasis on physical health. As machinery for the advancement of mental hygiene in the community, he desires nursery clinics, where children up to the age of five can be observed; child-guidance clinics for the maladjusted older child; and out-patient clinics for mental patients, in association with general hospitals and in close coöperation with schools, charitable organisations, law courts, industrial concerns, and mental and general hospitals. He does not hold it necessary to wait until a certain number of beds are provided in the general hospital; the establishment of more clinics of all kinds would, he thinks, create a further demand for the type of clinic that proves most useful. Every local mental hospital could offer some help in the way of coöperation with the local general or cottage hospital. The thesis of these lectures is that a psychiatric clinic for both in-patients and out-patients is the keystone of the psychiatric arch. With such clinics, numerous on the Continent and in America, this country is still inadequately supplied.

PRINCESS ALICE MEMORIAL HOSPITAL, EASTBOURNE. During a visit to Eastbourne last week the Prince of Wales laid the foundation-stone of the new buildings of this hospital.

ANNOTATIONS

DISCIPLINE UNDER N.H.I.

INSURANCE committees and approved societies are fully justified in drawing attention to the cumulative evidence of the abuse of national health insurance benefits. In so far as medical practitioners may be found to blame, the medical profession has a strong incentive to join in restraining any wastage of the approved societies' funds. Those who favour the principle of salaried service will be helped in argument if the panel practitioner shows himself careless of the prescribed Terms of Service which he has undertaken, or half-hearted in his resistance to pressure from insured persons. Public opinion, it is safe to say, is as yet no more attracted by the idea of a salaried service than is professional opinion. But if avoidable abuses continue, and if the Minister of Health is driven to take drastic action, that idea is certain of advancement as a potential remedy. It therefore seems worth while to re-examine the situation somewhat closely. For this purpose we offer on p. 87 a study of a sample of the disciplinary work under the National Health Insurance Act as revealed in a single sitting of the London Insurance Committee.

THE KETOGENIC DIET FOR EPILEPSY.

THE method of treating epilepsy by the ketogenic diet is not easy to master, nor is its theoretical basis established. The process of maintaining a ketogenic ratio, once established, by food adjustment is laborious for the physician and the cook, and unpalatable, if not actually unpleasant, for the patient. Is it worth it? Dr. F. B. Talbot, in a book reviewed elsewhere in this issue, quotes the results obtained by himself and three other observers, covering in all a series of 208 epileptic children at the Massachussetts General Hospital. In rather less than 40 per cent. of these children, application of the diet was followed by complete relief of symptoms. Among adults, a lower percentage must be expected. It is agreed that the method must be thoroughly understood and conscientiously carried out, or left alone altogether. The only definite contra-indications would appear to be a low grade of mentality, or an unwillingness to coöperate on the part of the patient. The degree to which the diet should be pushed, and the duration of the treatment are indicated by the fit incidence. If the protein and vitamin content of the diet are carefully watched, and a small dose of calcium be added as a precaution, Dr. Talbot believes that prolonged ketosis has no prejudicial effect on growth or development; nor need treatment be interrupted in the case of intercurrent disease. He gives a clear account of the metabolic processes involved in the production of ketosis and of the maintenance of the requisite ketogenic ratio by food adjustment. Once the principles have been grasped, their application is made easy by an admirable series of tables. The normal height and weight of children of various ages and of adults are given, and the important point is made that in calculating caloric requirements, the normal weight of a patient of the given age and height should be taken. Otherwise the obese child will receive extra calories which he does not need, and the thin child be deprived of calories which he does need. Once the total calorie requirement has been determined by this and other considerations in the individual case, the daily ration of protein, fat, and carbohydrate needed to arrive at the ketogenic ratio aimed at can be calculated from a special table derived from previously unpublished data by Luther and Bartlett. Tables are also supplied to show the composition of the various foods, together with their ash and vitamin contents, and finally a series of complete specimen dietaries, so that all the material for building up a diet on this basis is here provided.

Why the ketogenic diet should prevent the occurrence of attacks is not known. Whether acetone or some other product of incomplete fat metabolism has a specific action, whether the diet causes a shifting of the acid-base balance in the blood or a lessening of its CO_2-combining power, or whether the lowered blood-sugar content is a factor—these things remain a mystery at present. The position as to blood-sugar is anomalous in that ketosis with a lowered blood-sugar prevents fits, while the rapid hypoglycæmia that follows insulin injection often gives rise to fits. In the June issue of the *Bulletin* of the Johns Hopkins Medical School, Dr. E. M. Bridge and Dr. L. V. Job discuss the mechanism by which the ketogenic diet acts. They incline to attribute the benefit to the régime to the removal of extracellular fluid from the body, and to intensify this action they recommend a preliminary fast of five days' duration before starting treatment, water only being allowed. No one who has studied the recent work of J. L. Gamble, I. McQuarrie, and Temple Fay can ignore the importance of dehydration in the treatment of epilepsy. As Dr. Talbot himself points out, low salt diets, shift of the acid-base balance of the blood towards the acid side, the production of ketosis, whether by fasting or by the use of a special diet, limitation of the fluid intake, and the use of cathartics are all procedures which have, or have had, the reputation for controlling epileptic attacks, and they all have one common effect on the tissues, dehydration. It may well be that the elaborate calculations and devices that are involved in the production and maintenance of ketosis achieve their object in epilepsy solely by lessening the body fluids. If this be so, we may hope that some method more simple and more congenial to physician and patient alike may come to hand.

MATERNAL MORTALITY AGAIN.

THIS year, for the first time, the National Conference on Maternity and Child Welfare was held elsewhere than London, the place selected being Cardiff. The fine City Hall provided an admirable setting for the meetings, any acoustic defects having been largely obviated by the use of microphones. The Principality was well represented among speakers. The presidential address was delivered by Mr. John Rowland, Chairman of the Welsh Board of Health. Speaking of maternal mortality, he said that to those who talked about the "irreducible minimum of maternal deaths" or the "normal order of things" he commended the study of the interim report of the Committee on Maternal Mortality and Morbidity, published last year. From the investigations there recorded it appeared likely that at least one-half of the deaths among women in childbirth could be prevented if conditions were more favourable. Efforts must extend in many directions. The obstetric training of *medical students* must be improved *and* the midwifery service developed. There must be more antenatal supervision, and consultants and hospital beds must be available for the difficult cases. There was room also for extended educational measures, wisely directed, to inspire the patient with confidence. He welcomed the presence of the conference, especially as a stimulus to Welsh endeavour, for the maternal mortality-rate of Wales is about 40 per cent. higher than that of England. This may be partly accounted for by the rugged, mountainous nature of the country, the sparsely populated areas with difficulty of transport, and the exceptionally hard conditions under which the industrial population in the mining valleys of the south are living.

Speakers at the conference showed a notable consensus of opinion in favour of giving the general practitioner a central position in any national maternity service. Dr. Gilbert Strachan (Cardiff) pointed out that all the schemes put forward by different groups of people have much in common, all concentrating on the necessity for improved obstetrical education of medical students and midwives, the importance of antenatal supervision, the necessity for more hospital accommodation for maternity cases, and a proper consultative service. Sir Ewen Maclean (Welsh National School of Medicine) and Mr. J. Bright Banister (London) both deprecated indiscriminate and ill-considered criticism of the medical profession, pointing out that teachers of obstetrics have been fighting for generations to obtain a larger proportion of the students' time for obstetrics and gynæcology. Sir Ewen Maclean suggested that the real difficulty of shortage of teaching material might be partly met by a system of conjoint teaching of medical students and midwives, to the advantage of both. Mr. Banister, while emphasising the importance of a postnatal examination within three weeks after childbirth, expressed his belief that it is erring on the side of too much protection to insist on regular postnatal supervision for every patient, though, of course, any disablement complained of should be corrected. Too much may, he thinks, be made of slight anatomical deviations from the normal which in no way incapacitate a woman from being a useful member of society. Similarly, Dr. W. G. Savage (Somerset), speaking at a joint meeting of the Association of Maternity and Child Welfare Centres and the National Baby Week Council, questioned the need for submitting every pregnant woman to two antenatal examinations by a doctor. The danger of creating a pathological atmosphere, detrimental to the patient's peace of mind, must not be ignored. He holds the midwife to be the pivot of the maternity service, and therefore lays great stress on improving her capability and status. In Somerset he has introduced a system of flying clinics, under which an experienced woman obstetrician visits any district to which she is called by a midwife or health visitor for help or advice. Dr. Thomas Evans (Swansea) thought that in towns a more efficient service would be secured by the employment of specialists rather than general practitioners, basing his argument on the satisfactory results obtained in certain institutions and districts where teams of specialist workers have carried on large practices with a maternal mortality-rate of under two per 1000. Dr. F. Ivens-Knowles (Medical Women's Federation) emphasised the importance of skilled antenatal care, and said that an investigation of many institutions showed that the mortality was ten times as high among those of the patients admitted as emergency cases who had not had such care before admission. A number of speakers called attention to the fact that safe childbirth depends on other factors besides obstetrics. Dr. Garland Collins (West Ham) mentioned the prevalence of drug-taking on the part of women and its disastrous effects; Dr. G. C. M. M'Gonigle (Stockton-on-Tees), whose paper was read by Dr. Ralph Picken, attributed particular importance to the nutrition of the expectant mother, and had had encouraging results from antenatal administration of vitamins A and D to the women. Dr. Dunstan Brewer (Swindon) emphasised what previous speakers had already indicated, that the presence or absence of confidence exercises a powerful influence on any woman's chances of a successful and uneventful labour. His views, with those of Mr. Bright Banister and Dr. Savage, noted above, are shared by all experienced obstetricians and midwives, and suggest that constant reiteration of the high mortality and morbidity associated with childbirth has its dangers. While it may be desirable to stimulate public concern, in order that more money shall be available for social services to combat these evils, the prospective mother is likely to be disheartened. It is impossible to represent a process as physiological while at the same time insisting that for months before and after, as well as during, parturition, the woman must be under constant supervision. There is sound sense in the view that postnatal attention should be reserved for those who complain of any disablement.

THE LIMITS OF PREVENTIVE MEDICINE.

It is refreshing, in times when the jargon of health propaganda far outstrips its accepted principles, to hear a medical officer of health admit that the greatest obstacle to the successful practice of preventive medicine is our lack of knowledge. At the Congress of the Royal Sanitary Institute, held at Glasgow this week, Dr. Ralph Picken, of Cardiff, showed that whatever the aspirations of local authorities, the contribution of the newly acquired municipal hospitals to preventive medicine must at present be confined mainly to the provision of opportunity for scientific research and teaching. The most that can be done is to provide ample accommodation for observation in the attempt to detect at an early stage conditions which are curable only if treated before they have reached a crucial phase. Dr. Picken pointed out that in all countries far more money is spent, and under present conditions must be spent, on the curative than on the purely preventive medical services. Even in Russia, where the revolution was followed by a determination to alter the old bias in the direction of prevention, the distribution of funds for health work in 1925 was 77 per cent. for hospitals and out-patient departments against 23 per cent. for protection of motherhood and infancy, sanitary and hygienic education, sanatoriums, campaigns against contagious diseases, psychiatric treatment, and so forth. Even a communist state then had evidently found it necessary to spend most of its available funds on treatment, in spite of its lip-service to prevention.

In order to ascertain the type of case for which provision must be made in municipal hospitals, Dr. Picken reviewed first the demands made on the poor-law hospitals which they replaced, and, secondly, the waiting list on May 11th, 1931, of the Cardiff Royal Infirmary, on the assumption that this waiting list would be typical of voluntary hospitals of this class. The Royal Infirmary (apart from its convalescent home and a maternity branch) contains 380 beds, of which only 105 are in medical wards. It is thus not because an undue proportion of beds are allocated to medical treatment that only 24 patients are awaiting admission to medical, against 1543 to surgical beds. The great majority (77 per cent.) of waiting patients suffer from diseases such as hernia, hæmorrhoids, appendicitis, gastric and duodenal ulcers (52 bound for surgical, only eight for medical wards), cataract, chronic diseases of the ear, nose, and throat, and endocervicitis and allied disorders. It is in the relief of such patients, for whom voluntary hospitals will always find it difficult to provide enough accommodation, that Dr. Picken sees one of the main functions of the municipal hospitals, for in the widest connotation of the word such treatment is preventive, if only of more acute disorders. If all medical officers of health advise their authorities in this sense, coöperation between the two kinds of hospital should lead to the foundation of a science of preventive medicine on a broader basis than has hitherto been possible and to its speedy development.

THE JEWISH DENTAL CLINIC.

THE annual report of the work of the Jewish Health Organisation appears under the title "Public Health Work in the Jewish Community." It includes many interesting activities such as public lectures, inspection of evening schools, and the well-known child-guidance clinic. It is satisfactory to learn that the society has been restored to solvency and even provided with a surplus. The most recent development is a dental clinic for adolescents, which was opened on Nov. 20th last. The committee felt that much of the valuable work of the school dental service failed in its object owing to the lack of supervision for adolescents. Even when the young person is old enough to join the National Health Insurance scheme, dental benefit is only provided by some approved societies, and then after an interval of several years. The Jewish dental clinic, called the "Prunella Treatment Centre," holds sessions in the evening after normal working hours in an attempt to fill this gap in the health service of the country. Patients are seen by appointment, and every member under the scheme is inspected at least once a year. Inspection and treatment are combined with dental hygiene education. The clientèle is obtained through societies and clubs, the affiliation fee being provisionally fixed at a shilling a year, with a minimum of £2 per institution. The clubs are visited by the dentists to give talks on oral hygiene and to make inspections and arrange appointments for those requiring treatment. Already seven clubs have been visited and 166 young people examined. Of these no fewer than 161 required treatment, thus indicating the need for the service.

SUPRARENAL CORTEX IN ADDISON'S DISEASE

THE discussion on hormones and the diseases of the ductless glands at the recent meeting of the Association of American Physicians centred largely on the effect in Addison's disease of the potent hormone extracted from the suprarenal cortex. Attempts to elucidate the inter-relation of the adrenal and the thyroid glands by giving the extract to patients with Graves's disease were also described. So far, however, the effect on these patients seems to have been mainly subjective—i.e., they felt better but their metabolic rate was unchanged. With regard to Addison's disease not much progress seems to have been made since we last commented on this interesting work.[1] Papers were contributed by Dr. W. W. Swingle and Dr. J. J. Pfiffner, of Princeton, who described the method of extraction which they have found to be the most effective after extensive trials, and by their various clinical collaborators. There seems still to be considerable difficulty in obtaining an adequate supply of the extract and treatment has had to be discontinued in urgent cases for lack of it. Dr. L. G. Rowntree recorded the use of this treatment in 20 cases of Addison's disease, with five deaths. Two patients who had adequate treatment did not respond. Those who improved showed gain in weight and strength, disappearance of anorexia, nausea, and vomiting, decrease of pigmentation, gain in sleep, change of outlook, and desire to go back to work. The hormone was administered intravenously, the dosage being 3·5 c.cm. in a day. The preparation used by him had some tendency to sensitise the patients to adrenalin. Dr. G. A. Harrop (Baltimore) reported definite improvement with the extract in three cases, Dr. Allbright (Boston) in one case, while Dr. T. R. Boggs (Baltimore) described his success in one case with the whole gland, administered in a capsule insoluble in the stomach. The patient was a Scotch woman living in Jamaica, and her pigmentation had been so deep as to cause social embarrassment to her husband. Within four weeks after beginning treatment, which also included large doses of calcium, the blanching of her skin was considerable and a report received after her return to Jamaica was satisfactory. Dr. Rowntree reiterated his belief that the extract from the cortex is a potent remedy for Addison's disease, specific though not infallible, but he emphasised the need for many more records of cases before this form of treatment can be evaluated.

EMBRYONIC INJURIES.

THE late Dr. T. S. P. Strangeways evidently had a sure instinct when he saw towards the end of his life that tissue culture was likely to be a valuable weapon in experimental pathology. Under the guidance of Dr. H. B. Fell a number of valuable researches on normal growth and the mechanism of calcification have come from the laboratory which he founded. One of these is a singularly interesting contribution[1] by Dr. Janet S. F. Niven on the healing of wounds in the rudiments of bones, isolated from the embryo and allowed to grow and differentiate in tissue cultures; what the tissues do is therefore determined by themselves and is not subject to any influence from the rest of the embryo. If the femur from a five-day chicken embryo is cut across and the ends left in apposition, the wound is healed at once by proliferation of the cartilage cells and in 24 hours no trace of the cut can be seen or found in histological preparations; later on, normal differentiation of the cartilage occurs and bone begins to form in the usual way. In the early stages, therefore, cartilage cells have a remarkably high capacity for repair. But this is soon lost. If a femur rudiment from a six-day embryo is similarly divided across the shaft, the cartilage immediately adjacent to the cut undergoes some change which makes it opaque instead of semi-translucent, and although the two halves of the rudiment go on differentiating normally the cartilage does not unite. The site of the cut remains obvious and is outlined on either side by a zone of degenerated cartilage cells. The fragments are united and an effective mend made by proliferation of the periosteal cells and the neighbouring connective tissue, aided sometimes by an ingrowth of the osteoblastic layer of the periosteum and the production of osteoid tissue. The embryonic limb in fact does what the adult body does; if it cannot achieve its end by one means it does it by another. In rudiments from older embryos in which a bony sheath is already present the cartilage takes no active part in repairing a fracture. Indeed the osteoblastic tissue which comes in through the gap takes an active part in bringing about the absorption of the cartilage, which can take place without the invasion of blood-vessels.

---

[1] See THE LANCET, 1930, i., 652.

[1] Jour. Path. Bact., 1931, xxxiv., 307.

The further development of these injured rudiments proceeds in a normal way and a continuous sheath of periosteal bone completely covers the site of the injury. The morphological differentiation is also normal, and from an injured rudiment of, for instance, the femur a properly shaped bone emerges with head, neck, and condyles as they should be. In the chances of tissue culture it often happens however that the two fragments are not in perfect alignment and the shaft into which they develop is in consequence curved. It is of exceptional interest to learn that the formation of periosteum and osteoid tissue is considerably greater in the concavity than on the convexity of the head—an observation which is difficult to harmonise with the common belief that the similar condition seen in rickets is due to pressure from use.

THE CONTROL OF MALARIA IN SOUTH AFRICA.

We learn from a South African correspondent that Prof. N. H. Swellengrebel, of Amsterdam, who was called into consultation by the Government of the Union of South Africa for advice on the presence and conditions of endemic malaria in Natal and the Transvaal, has presented an exhaustive report. He is hopeful that malaria control in South Africa will be achieved more simply and cheaply than has been anticipated. The main carrier of the disease in the Union, *Anopheles costalis*, is, fortunately, highly selective in its breeding places, choosing muddy pools and drains open to the sunlight in preference to swamps, morasses, and rivers. This predilection makes the control of breeding places an economic possibility. Whereas it was feared that larvicides would have to be used lavishly over the whole countryside, Prof. Swellengrebel believes, as the outcome of careful investigations, that paraffin applied to comparatively few selected spots, easily identified, is likely to check the spread of the disease. One of the major recommendations is the use of malaria-tolerant native labour, to be drawn from highly malarious areas where investigation has shown that only the children suffer from the disease, adults being immune. A corollary of this recommendation is that no steps should be taken to reduce the incidence of malaria in these areas. Prof. Swellengrebel makes it clear that his advice is based only on present knowledge; any policy adopted must be flexible, since new facts materially altering the outlook may be revealed by research, which must be actively pursued. He estimates that malaria control in Natal will cost the sugar industry one-quarter per cent. of its gross income—an infinitesimal sum compared with the losses the disease has already caused the industry, and will continue to cause if not controlled. He points out that antilarval measures, although indispensable for the complete eradication of malaria, should not be regarded as the only means available for control of the disease in South Africa, and that there was no reason for discouragement if further experience should prove the impossibility of their general application. Besides *A. costalis* and *A. funestus* a third anopheles, *A. pretoriensis*, had once been found to be infected. This species breeds in swamps, and if subsequent research shows it to be a potent malaria-carrier, the methods of combating infections will be greatly complicated. It is likely, however, that the outcome of investigations now being made will confirm the evidence hitherto available, that the species is not a dangerous vector of malaria in South Africa. Among Prof. Swellengrebel's recommendations for Natal are the organisation of health committees, a centralised medical and hospital service for the whole sugar belt, a system of medical examination of recruited labour, government help for the provision of malaria-tolerant labour, an adequate quinine distribution, and instruction on malaria in native schools. For the Transvaal he proposes a unit for malaria control and research, a field station for malarial control, instruction of the public in general, especially of school-teachers and farmers' wives, by district surgeons and district nurses, and finally that natives in epidemic areas should be trained, as they are now trained in Natal, to initiate treatment in native reserves and to promote a knowledge of malaricology. The report makes it amply clear that no dread of malaria need prevent the settlement of people of European descent in any part of the Union otherwise suitable for their reception.

A PORTRAIT OF DR. ALFRED COX.

It is intimated that Dr. Alfred Cox will retire from the position of Medical Secretary to the British Medical Association, which he has long occupied with distinction, at the centenary meeting of the Association in London next year. A group of the Association are arranging for the painting of a presentation portrait, and a general meeting of these members will be held on Saturday, July 18th, at Eastbourne, to elect an executive committee with the usual officers, and decide upon the organisation for the collection of subscriptions.

A SHORT COURSE IN TROPICAL MEDICINE.

The authorities of the London School of Hygiene and Tropical Medicine announce that they are about to modify the post-graduate course in tropical medicine. The five-months' course of intensive study hitherto in force, followed by examinations first for the certificate issued by the school and then for the Diploma of Tropical Medicine of the Conjoint Board, has been found to impose an undue strain upon candidates. Many of the colonial governments have found it difficult to release their medical officers for a sufficiently long period to enable them to combine what is in effect six months' study-leave with a much-needed holiday in this country. Further, the requirements of the colonial service are so urgent that a demand has arisen for a short course of instruction for recruits about to proceed overseas. After consultation with the Colonial Office and the Conjoint Board, it has been decided to divide the course of study into two parts: a three-months' course of clinical and laboratory instruction and a two-months' course in tropical hygiene. Each course can be taken independently, and the Conjoint Board is arranging for an examination to follow closely upon each course of study. The internal school examinations will be discontinued, and students will be encouraged to sit for the diploma examination. Application has been made to the University of London for recognition of the revised course. The new three-months' course includes clinical tropical medicine, applied pathology, medical zoology, and elementary bacteriology; the two-months' course includes instruction in the relation to tropical hygiene of bacteriology, medical zoology, anthropology, and vital and medical statistics. In order to meet the requirements of the modified course, the school has established a new division of clinical tropical medicine which can call on the combined resources of the Seamen's Hospital Society. The innovation will undoubtedly fill a need, and the facilities offered should make it easy for many more medical men and women to learn or revise the groundwork of tropical medicine, pathology, and hygiene.

CONTRIBUTORY SCHEMES AND HOSPITAL BENEFITS.

Whether a hospital contributory scheme should or should not guarantee definite benefits to the contributors is one of the most interesting problems which arises, if only indirectly, from a study of the replies received to a questionaire recently issued by the Central Bureau of Hospital Information.[1] It is not stated how many questionaires were despatched to those responsible for the management of contributory schemes and to hospitals interested in their establishment, but 456 replies were received, of which 126 were non-committal; 330 replies were thus available for analysis. Those replying were classified into four groups, of which Groups I. and II. embraced views based on experience of existing schemes, run respectively by outside organisations (Group I.) or by the hospitals themselves (Group II.); in Groups III. and IV. were included expressions of opinion from hospitals not at present associated with any contributory scheme, but favouring outside or inside management, respectively.

The questions asked included, among others, (*a*) the limits of income, if any, imposed on contributors; the majority favour a limit of £6 a week; (*b*) the weekly contribution—2*d*. or 3*d*. are the most popular figures; (*c*) the desirability of making payments out of funds raised by contributory schemes to members of honorary medical staffs; of those answering this question 109 objected to any such payment, while 41 agreed to the principle that payments might be made. In a number of schemes, however, the medical staffs are allowed to charge fees to all patients, whether contributors or not.

The most crucial of all the points at issue, however, arises indirectly from the question: On what grounds should the invitation to become a contributor be based? The subdivision in the classes (*a*) and (*b*) of each of the four groups is based on the replies to this question, of which samples are given. Broadly speaking, those advocating appeals on the grounds of insurance against illness in the future, of making sure of free treatment and maintenance in hospital for self and dependents, should illness occur, as well as on altruistic grounds naturally fall in each group into class (*a*), which provides, or aspires to provide, definite benefits to contributors; while those who advocate appeals entirely on altruistic grounds belong in each group to class (*b*) —those promising no stated benefits. It is interesting to note that of the 330 organisations classified 212 fall into Groups I. and II.—organisations with existing schemes—and among these 113 offer definite benefits, 99 offering no stated benefits. Groups III. and IV., hospitals with schemes only under consideration, include 118 hospitals, of which as many as 86 contemplate or recommend schemes offering definite benefits, only 32 believing in schemes which carry no stated benefits. It is recognised that the contributor may in any case have no legal right to treatment; but when the benefits of joining a contributory scheme are definitely stated, as they are in the leaflets issued in connexion with a large number of schemes, there can be no doubt that such statements provide some inducement to join. Where such inducements are offered it must be a matter of actuarial calculation, when data are available, whether a weekly contribution of, say, 3*d*. a week is adequate to meet the benefits offered.

---

ANNUAL HEALTH REPORTS FOR 1930.

We publish in this issue the first group of notes on the annual reports of medical officers of health for 1930. They have an unusual interest since 1930 marks the eve of a new period of hope. Important legislation, notably the Local Government Act of 1929, began to operate on April 1st, 1930, while the Housing Act of 1930 and the Mental Treatment Act 1930, came into operation on Jan. 1st, 1931. Under the Local Government Act, the magnitude of the task of county councils and county borough councils must vary greatly, according as to whether they succeed guardians of the progressive or conservative type. Judging from the first reports to hand from the county boroughs the transfer of duties is taking place smoothly. The county councils have a task which will operate much more gradually. On all sides there is a desire to secure harmonious working with the voluntary hospitals and so to get the best possible value out of each hospital for the community. Under the Housing Act a determined attempt is to be made to get rid of slums and to rehouse the slum-dwellers. The five-year housing programmes, which are due from each local authority, will be studied and their progress followed by many not directly concerned with the district. Under the Mental Treatment Act it will be found that many authorities had in readiness for Jan. 1st, 1931, arrangements designed to bring close coöperation between mental and general hospitals, such as the establishment at general hospitals of mental out-patient clinics conducted by experts, and the provision of hospital wards for voluntary and temporary mental patients without the stigma involved by certification. The Registrar-General has not made his usual estimate of the populations for this the last year of the intercensal period. We shall shortly know how far the estimate used in 1929 and previous years deviated from actuality. Doubt was thrown on the accuracy of the last census from the beginning owing to the fact that it had to be taken at the end of June, and involved estimates of the holiday movements of the population. Several medical officers of health have always preferred to use locally made estimates and it will be instructive to see whether they or the Registrar-General have been nearer the mark.

Liverpool Royal Infirmary.—With a total of 336 beds, 6850 in-patients were admitted last year, which, for the seventh year in succession, constitutes a record. Their average stay was 15·25 days, and their average weekly cost £2 15*s*. 10½*d*. There were 51,267 out-patients, again a substantial increase; they cost 4*s*. 5¼*d*. per head. The average cost per occupied bed was £145 13*s*. 7¼*d*. The total income of £51,925 fell short of the expenditure by £2646, and the accumulated deficit on the general account is now £35,805.

PANEL AND CONTRACT PRACTICE

PITFALLS OF PANEL PRACTICE.

A SAMPLE OF COMPLAINTS.

THE following paragraphs summarise a batch of 12 cases taken from the published proceedings (No. 6, dated June 25th) of the London Insurance Committee sitting to consider the Report of the Medical Service Subcommittee. Of these dozen cases, which give a cross-section of the panel doctor's work, five relate to allegations of irregular certification or other breach of regulations, five to complaints of delay or inadequacy of treatment, and two to minor matters. The broad result is that one practitioner is found grossly negligent, is severely censured and heavily penalised by deduction; two others are found to have broken the Terms of Service and are penalised in a lesser degree; the rest are either exonerated or not found so seriously to blame as to merit penalty. Even a brief summary of the cases must be somewhat diffuse if it is to show fairly the incidents and the different points of view upon which the London Insurance Committee is passing judgment. Reasons for setting them out in detail are given in our annotation columns.

COMPLAINTS OF IRREGULAR CERTIFICATION.

Of three instances in our sample one is an approved society's complaint that an insurance practitioner gave an insured person's wife a certificate dated March 3rd though he had not seen the patient for a fortnight. At the hearing it appeared that other certificates had been given irregularly. The practitioner said he had seen the patient on certain dates, but the patient's wife could not remember the particular days of his visits beyond the first two or three; she said she had herself been to the surgery to obtain certificates for her husband. The practitioner, whose good faith the Committee accepted, said he understood the local agent of the approved society called at the insured person's house every Wednesday and that the patient was concerned to obtain a weekly certificate on the previous day in order to substantiate the claim to weekly payment of benefit; in giving the certificates, his sole object was to assist his patient to obtain his money. The Committee points out that Rule 9 of the Medical Certification Rules forbids the practitioner, having issued a certificate under the Rules, to issue another without again examining the patient. This, they justifiably observe, is the essence of the system of certification under the Act—viz., that a certificate shall be issued only on a fresh examination of a patient. The facts were admitted as to three certificates. The practitioner's explanation was not accepted as an excuse for a violation of the Rules; he failed properly to appreciate that the certificate contained a statement of fact and he could not have been ignorant that he put his signature to statements which were not true. He committed a breach of the Rules and consequently also of the Terms of Service for Insurance Practitioners. He is to be warned of the necessity of strict adherence to the Rules and the Minister of Health is asked to withhold a sum of £2 from the money payable to the Committee with a view to that amount being deducted from the practitioner's remuneration.

Another instance related to three certificates dated Feb. 16th and 23rd and March 2nd issued by a panel doctor to the insured person's daughter without his having seen the patient within the previous 24 hours. The proceedings stated that the doctor seemed to think all would have been in order if he had inserted the date of the examination as well as the date of signature; he appeared not to be acquainted with the provision in the Medical Certification Rules that a certificate should be given either at the time of the examination or within 24 hours afterwards. He had also broken Rule 9 in giving a further certificate without a fresh examination. The Committee ascertained that the approved society agreed that there was no doubt that the patient was in fact incapacitated from work. The Committee did not question the doctor's good faith; it appreciated that he had signed merely in order to assist the patient to obtain his benefit and to have the necessary document available when the agent of the society called. As in the instance already mentioned, the practitioner is to be warned of the necessity of strict adherence to the Rules and there is to be a deduction of £2.

The third instance concerned a First Certificate issued by a practitioner's assistant, not bearing a stamped impression of the practitioner's name and address as required by Rule 7 (4) of the Medical Certification Rules. The Committee seems to have accepted the doctor's explanation (that this must have been due to his assistant's misunderstanding) and his assurance that the assistant had now been given adequate instructions. There was a further point as to a Final Certificate, personally given on Tuesday, March 31st, indicating that the insured person would be able to resume work on the following Monday. The approved society informed the insured person that, under the Regulations, it could not accept this certificate as a "declaration off" for Saturday, April 4th. The patient then submitted a Voluntary Certificate (Form Med. 40 F) in which the doctor said he had examined the patient on April 6th and that the patient remained incapable of work up to that day; this Voluntary Certificate was dated April 18th. The practitioner at first said he thought he must have filled up the Final Certificate of March 31st in error for an Intermediate Certificate. At the hearing he withdrew this explanation and said that, on further consideration, he thought that when he saw the patient on March 31st he found the patient's inflamed leg nearly well and believed the patient would be quite fit to resume work on the following Monday; he thought he must have realised that Tuesday, March 31st, was in the week before Easter and he must have had in mind the question of covering the holiday period. As to the statement in the Voluntary Certificate that he examined the patient on April 6th, he had accepted in all good faith the insured person's statement in this report and had assumed that the patient must have been seen by his assistant on that day. The Committee finds that he contravened Rule 6 which allows the doctor, if of opinion that a patient is not fit to resume work immediately but will be able to do so on the second day after the examination (in urban areas), to issue a Final Certificate and to enter in the appropriate space on the certificate the date when he thinks the patient will be fit to resume work. In the case under review the doctor issued the certificate on a Tuesday and intimated that the patient would be fit no less than six days later. Impressed, however, by the practitioner's frankness, by his assurance that this was the only certificate he had given of this nature, and by his statement that in giving certificates he does not allow himself to be governed by any but medical considerations, the Committee finds no other action necessary except to impress on him the need of strict compliance with the Rules.

DEFAULT IN KEEPING RECORDS.

In one case the Minister of Health drew attention to a panel doctor's failure to keep proper medical records of the diseases and treatment of his insured patients as required by Clause 9 (12) of the Terms of Service. A Regional Medical Officer examined 223 record cards and found that only eight cards (or 3·58 of the whole) bore entries of attendances or visits for the year 1930. The Minister has considered exercising his power, under Article 41 of the Medical Benefit Consolidated Regulations, of withholding an appropriate portion of the practitioner's remuneration, but thinks it possible that the practitioner has not appreciated the full extent of his duties. No action is therefore taken at present except to warn the doctor that his cards will again be inspected in the coming 12 months and that, if they are then found improperly kept, a substantial sum may be withheld

QUESTION OF ASSISTANT.

One case, referred by the Medical Benefit Sub-committee, arose over the question of deduction from the practitioner's remuneration by reason of his having been without an assistant for part of the first quarter of the year 1931. The facts were apparently admitted and the practitioner seems to have agreed to the withholding of an appropriate sum. He had employed an assistant, with the Committee's permission, in a practice which showed 2678 insured persons on his list at the beginning of the year. His remuneration was calculated on the number stated. The assistant left his employ on Feb. 12th; no other assistant had been engaged and there appeared no intention to engage another until the end of September. He had been without an assistant for about one-half of the first quarter of the year, and he recognised that he was not entitled to remuneration for the whole of the quarter in respect of the additional number of insured patients included in his list by virtue of his employment of an assistant. The amount in question was £5 12*s.* 9*d.* and this is to be withheld. No question arises as to his remuneration for the second and third quarters of 1931, as the practitioner will be paid for these on the full number of insured persons on his list if the figure does not exceed the maximum permitted by the Allocation Scheme; if it does, his remuneration will be calculated on the maximum number.

COMPLAINTS OF DELAY AND INADEQUATE TREATMENT.

The five instances of complaints that a panel practitioner has been dilatory or inadequate in treatment of a patient are necessarily more vague than the foregoing instances where some specific allegation of a breach of rule or regulation has been in question. Disputes about treatment will naturally vary widely with the disputed facts of particular cases. The patient's relatives are unlikely always to agree with the practitioner as to the exact degree of urgency represented to him. It is easy to be wise after the event. In our first instance of this class a patient visits the doctor's surgery on the evening of Feb. 23rd complaining of general pains. The insurance practitioner's partner (called "Dr. A" in the proceedings) finds him slightly feverish and diagnoses influenza; he gives a certificate of incapacity on this ground next day. The patient's son says the doctor promised to call and see his father; the doctor denies the promise and the Committee thinks it very likely that no such promise was made. The patient remained in bed; nothing happened till Feb. 27th when he appears to have developed a form of delirium. His wife being ill in the house with bronchitis and pneumonia, his daughter, the only adult then available, became alarmed and sent for the police. The son was also called and found his father shouting and singing. The police sent him for his father's doctor. He went to the surgery at 8 P.M. (where patients were waiting), saw the dispenser and asked if the doctor could come at once as the case was urgent. The dispenser told the son to see the doctor personally and take his turn in the surgery. The son waited 20 minutes before he reached the consulting-room. It was not clear what happened next. The son said he told Dr. A his father was delirious and was going mad and that the police were in attendance; Dr. A denied that delirium was mentioned. The doctor seems to have said that he "did not deal with madmen" and that he did not "take orders from the police." The son went away; the police sent for the relieving officer; the patient was taken forthwith to hospital and died there on the 29th from pneumonia. The doctor had called at the house two hours after receiving the request, but had not told the son he would call. The Committee had to consider the allegation of the doctor's delay in responding to an urgent request for his services. The evening hours at the surgery were from 7 to 9.30; the doctor was very busy at the time and had to decide whether to interrupt work at the surgery or to defer his visit till that work was finished. Was the two hours' delay unreasonable? The Committee finds that Dr. A committed an error of judgment in not going to the patient earlier, but the incident is held to fall short of amounting to a failure to comply with the terms of service. The Committee adds that arrangements for dealing with urgent cases at this surgery should be improved, urgent messages should be brought to the immediate notice of the doctor on duty, that Dr. A was not so considerate or careful in inquiry as he should have been, and that this led him to make the error of judgment laid to his charge.

Another complaint of delay was complicated by the circumstances that the patient was dead when the doctor was summoned and that there is no Regulation which requires an insurance practitioner to attend for the purpose of viewing a dead body. The wife of the patient had gone to the surgery one evening and reported her husband seriously ill "being unable to breathe without great difficulty." She obtained a prescription for him but did not think it necessary that the doctor should call. Next morning the patient was found dead in his bed. A neighbour went to tell the doctor and the widow took a second message at 7.30 A.M. The practitioner replied (through a maidservant) that he could not call immediately and in any case could do little since he could not certify the cause of death; he would have to inform the coroner. An hour later the widow brought a note expressing doubt whether her husband was dead. She was informed that the practitioner had gone out and she was advised to obtain the services of another doctor The practitioner received the note later in the day but not before he had called at the patient's house. The Committee, though strictly perhaps exceeding its jurisdiction since admittedly there is no legal obligation on an insurance practitioner to attend a dead man, expresses the view that the common practice of the medical profession and the ordinary dictates of humanity suggest that a doctor would not hesitate to pay a visit even after the patient's death for the peace of mind and comfort of the relatives. In this sense the Committee thinks there was delay and that the practitioner's explanation is unconvincing; but it is unable to find that the Terms of Service were infringed.

Another instance concerns a patient, aged 22, who had often been under the care of the insurance practitioner and his assistant (called "Dr. A" in the report) for gastric trouble. Early one Sunday last April the patient had an attack of severe pain in the stomach and told his father. The father had to go out to work; on returning and finding his son no better, he went to the surgery and saw Dr. A about 6 P.M. No request was made for a visit; the possible cause of the trouble was discussed and Dr. A prescribed a bismuth mixture and aperient pills, asking to be informed of the patient's condition next day. On the next evening Dr. A was sent for; he interrupted his surgery work to pay the visit. He examined the patient, prescribed, and again asked to be kept informed. He had a report next day and gave further advice. On the day following, Dr. A was telephoned for, visited the patient and advised his removal to hospital where intestinal obstruction was diagnosed. An operation was performed and strangulation of the small intestine was revealed. After the operation the patient collapsed and died; the coroner found death due to toxæmia following intestinal obstruction, combined with the shock of the operation. At the inquest the patient's father and mother for the first time expressed dissatisfaction with Dr. A's conduct, complaining that he did not call on the Sunday night. The Committee however finds that the father did not request a visit on that Sunday but was satisfied with a prescription. The Committee accepts Dr. A's statement that he would have gone if asked; it points out that he did go promptly twice when requested. Yet, while admitting that it is easy to be wise after the event, the Committee cannot entirely exempt Dr. A from criticism for not seeing the patient on the Sunday evening before prescribing. It is emphasised that the Terms of Service oblige a practitioner to visit any patient whose condition so requires. This means that a patient must be visited at his home, if his condition requires it, even though no request is made. Prescription without seeing the patient is naturally deprecated, though it is recognised that here Dr. A had previous knowledge of the patient's type of illness and was led to infer a recurrence. The Committee decides that there was no failure to comply with the Terms of Service.

Judged by the penalty, the gravest case before the Committee was one in which the practitioner discontinued treatment without warning. A lad, temporarily residing in London, was on the list of a doctor in Surrey. He was taken ill on March 4th and was visited next day. His mother explained his position in insurance; the boy's medical card was handed to the practitioner but not taken away by him. Influenza was diagnosed and an insurance certificate of incapacity on that account was given. On the 6th the doctor visited the patient and recommended removal to hospital; the mother demurred, saying she felt quite capable of looking after her son. That evening the mother sent a message reporting pain and asking for something to relieve it; the doctor advised a plaster and promised to call next day. He did not call till a day later (the 8th) when pneumonia was found to have developed. The mother had raised the question on the 6th of having the services of a district nurse but the doctor thought this unnecessary. On the 8th the question of a nurse was again raised; the doctor advised how to obtain a nurse and a nurse was obtained. The doctor promised to call next day but did not; the nurse advised he should be sent for. The doctor told the messenger (the patient's uncle) that he was too busy but would come the following day (the 10th). On the 10th the uncle visited the surgery as an insured person to obtain a certificate for himself. The practitioner asked him to tell the mother that he did not intend to call any more. The mother with difficulty obtained another doctor who ordered removal to a hospital. The mother reported the facts to the Surrey Insurance Committee, who referred the case to the London Committee. As her report did not mention that her son had gone to hospital, an officer of the Committee telephoned to the insurance practitioner on the 12th, the case being treated as one of an insured person requiring treatment urgently. The practitioner called at the house and found the patient had been removed. The patient died on the 17th. The Committee finds that the practitioner thought he could wash his hands of the case because his original advice (that the patient should go to hospital) had been ignored. The Committee observes that, whatever he might do with his private patients, he had a definite obligation to provide treatment for his panel patients. The offence of discontinuing treatment in the Committee's view becomes gross "negligence" (as defined in Article 41 (5) of the Medical Benefit Regulations) when the practitioner gives no warning that he has given up the patient and when he ignores an urgent request. The Committee has seriously considered a representation for removal of the practitioner from the panel but contents itself with the finding of gross negligence and a recommendation of severe censure and the withholding of £50.

The last instance of alleged inadequate treatment is trivial and was disposed of without a hearing. A patient consulted her panel doctor for digestion trouble; he found her suffering from a septic molar tooth, prescribed for her, and advised a visit next day when he diagnosed stomatitis and said she would require dental treatment. That afternoon she consulted a dentist who is said to have expressed surprise at the practitioner's "incomplete diagnosis." She then consulted another doctor who, she said, told her her temperature had risen to 102° and advised her to go to bed. She sought to recover expenditure amounting to 31*s.* incurred during her treatment by the second doctor. The panel practitioner said that a possible cause of the sudden rise of temperature was influenzal catarrh, then prevalent; if the patient had informed him of this development, he would have seen her; but she did not give him the opportunity. The Committee observes that the patient thought the examination incomplete because he had not used a thermometer—as though the thermometer was the only means of determining a raised temperature. It finds that there is no reason to think the practitioner did not exercise proper care; the cost of treatment by the second doctor is therefore not recoverable.

OTHER CASES.

One of the two remaining cases in this sample of a dozen can be quickly dismissed. The patient's employers made a complaint but did not pursue it. The other case arose out of a doubt whether it had been represented to the insurance practitioner that the patient was an insured person. He treated her for tonsillitis, charging a fee of 8*s.* 6*d.* (paid at the time of the consultation), which included 1*s.* for a private certificate. The Committee finds that on the first day of the treatment the doctor was not told that the patient was insured; he therefore did not violate the Terms of Service. Exercising its discretion under Clause 7 (3) of the Terms of Service, the Committee directs the refund of 7*s.* 6*d.* and the crediting of the practitioner with the remuneration he would have received if he had attended the patient as a temporary resident. The sum of 7*s.* 6*d.* excludes the payment for the private certificate.

CONCLUSIONS.

These sample cases must represent a very small percentage of the total satisfactorily treated by insurance practitioners in the period and area concerned. We must not be content, however, to observe that it is a relief to find they are not more serious. The object of those who take part in the national health insurance system must be to avoid all possible cause of complaint. It will be useful to remember the Committee's views on particular points—e.g., that the duty to visit a patient is not excused merely because a visit is not expressly requested, that prescription without seeing the patient is strongly deprecated, and that the normal medical practice and the dictates of humanity may oblige a doctor to visit relatives for their comfort of mind though the patient is dead and though there is *no statutory duty*. But the most easily avoided matters of complaint are the direct breaches of a clear rule or regulation in such things as record-keeping and certification. The insurance practitioner must study the rules of the system which he undertakes to work; certificates are valueless if irregularly given; a member of an honourable profession will not put his name to statements which are not true. A casual and slovenly attitude towards certification, even though an element of fraud be absent, is dangerous for two reasons. It undermines the public faith in the medical profession which is entrusted with considerable responsibility in this respect by the State; it also exposes the individual practitioner to disciplinary action at the hands of the General Medical Council, of whose Warning Notice he cannot plead ignorance.

SPECIAL ARTICLES

REPORT OF THE BOARD OF CONTROL.

MENTAL HEALTH IN 1930.

THE passing of the Mental Treatment Act in July of last year and the steps taken to bring it into operation are naturally regarded by the Board of Control as the most important events of the year under review in their seventeenth annual report.[1] The report summarises the Act and remarks that some time must necessarily elapse before the effect of its far-reaching changes is felt, and calls for the coöperation of the public, the profession, and the local authorities to bring its benefits fully within the reach of those for whom they are intended. The Board's own steps to bring the Act into effective operation include a conference of representatives of local authorities last summer, a circular and memorandum to local authorities, and various explanatory circulars for local authorities and voluntary hospitals. The Board has given approval to licenced houses and nursing homes for a period of one year only, in order that special facilities for the intensive treatment of voluntary and temporary mental patients may be provided before the approval is renewed. The Board requires that every such house or home shall have a qualified mental nurse on its staff, and has also been concerned with the approval of special practitioners under the Act; up to March 31st last it had approved 2209 of these. The Board itself has been reconstituted, with five senior commissioners and 11 junior commissioners, on whom the task of visiting will principally devolve.

An inquiry into the working of the Act during the first two months of this year show, as would be expected, a very uneven provision in different areas. On the whole the figures are not unsatisfactory, but the Board considers the moment too early for either congratulation or disapprobation. The development of out-patient clinics is a most gratifying feature, perhaps because the difficulties of organisation are smaller than in other new ventures. The Board is particularly pleased that voluntary hospitals are showing willingness to appoint the superintendent of the local mental hospital a member of their staff, and hope that local authorities will reciprocate by appointing the honorary staff of the voluntary hospital consultants at the mental hospital. This interchange of staffs is an advantage, not only to the patients but also to medical education, clinical research, and the investigation of the problems of all departments. The Board is most anxious that teaching hospitals should admit voluntary cases in the earliest stages in order that students may learn to recognise incipient mental disease.

The Mental Hospitals during 1930.

The increase in the number of patients in public mental hospitals during the year was 2410, an increase that may be regarded as normal and that may be anticipated for some years to come. It does not, however, indicate any real increase in the incidence of mental disorders; it reflects the increase in the general population, a change in habits by which there is greater readiness to seek institutional treatment for old people who would formerly have been nursed at home, and the better feeding and more assiduous care which has diminished the death-rate in mental hospitals. The Board can find no justification for the suggestion that the conditions of modern life are conducing to mental breakdown.

Nevertheless, the increase is a matter of grave concern on account of the dangerously narrow margin of accommodation available. On Jan. 1st last there was, in the aggregate, overcrowding on the male side amounting to 452 beds and on the female side to 1635 beds. There were only 27 hospitals with 10 or more vacant beds on the male side and 19 with 10 or more vacant beds on the female side. Only two new mental hospitals are being built; one for Swansea and Merthyr and one for Middlesex at Porters Park, but Southend and East Ham are seeking a site for a joint hospital. The only hope of new beds in the immediate future is through the provision of admission hospitals and convalescent villas. The surplus accommodation rendered available by a re-allocation of poor-law institutions has proved to be much less than was anticipated. The Board stresses the lamentable effects of overcrowding, and points out how small an item in the budget of a local authority is the expenditure on public health services compared with that on highways and education. It hopes that, despite the difficult times, local authorities will realise the gravity of the situation and make plans for meeting it. It deplores the continued existence of mental hospitals without separate admission and convalescent units.

---

RESEARCH, SOCIAL SERVICE, AND NURSING.

The Board has given much consideration to the problem of research in mental hospitals and is most anxious that the work should be properly coördinated. An advisory committee is therefore being established; local authorities will be represented and expert assistance will be given by the Medical Research Council's Committee on Mental Disorders. Not less important, in the opinion of the Board, is a link between the work of mental hospital laboratories and that of universities and medical schools.

The Board regrets very much that in some areas the offer of voluntary organisations to assist with social service has been refused by the local authorities. The Board thinks it desirable that the voluntary spirit should be preserved and that this work should not be wholly professionalised, although in the larger area it is desirable to have a nucleus of trained and paid workers. Social work and after-care cannot, of course, be separated, and the real problem is the recruiting and training of the right type of worker.

The Board strongly approves the appointment of one local committee to deal with the mentally defective and with the mental hospitals. This will, however, greatly enlarge the work of the committee, and it is essential that some effective liaison be secured between this body and the Public Health Committee.

Many hospitals still find difficulty in securing probationer nurses, and the Board thinks that more might be done in the way of propaganda, through coöperation with the educational authority and perhaps also with the labour exchanges, to obtain selected candidates from distressed areas. The standard must not be lowered, for that will only increase the difficulty. The Board now has an inspector fully trained in both general and mental nursing, who is available for consultation on any deficiency in the arrangement of the hospitals which may deter nurses from joining or remaining in the service.

THE FIGURES FOR 1930.

On Jan. 1st, 1931, the number of notified insane persons under care in England and Wales was 144,161. The males were 44·1 per cent. and the females 55·9 per cent., a decrease of 0·1 in the proportion of males. Private patients numbered 14,404, rate-aided patients 128,846, and criminal patients 911. The recovery-rate for the year was 32·93 per cent., 29·87 per cent. for males and 35·38 for females. This is an increase of 0·87 for males and 0·72 for females above the rate for the previous decade. The death-rate of 6·71 per cent. is the lowest on record, being 1·33 below that for 1929. The rate was 7·43 per cent. in males and 6·13 per cent. for females. The alterations and extensions that received statutory approval during 1930 include admission hospitals at Denbigh, Banstead, and Hull; nurses' homes at Denbigh, Severalls, Chartham, Springfield, Netherne, East Sussex, the East Riding of Yorkshire, Bristol, and Leicester City; convalescent or other villas at Denbigh, Brookwood, Netherne, West Sussex, Winson Green, and Portsmouth; extensions of ward space at Long Grove, Salop, Netherne, Brighton, and Bristol; additions to other buildings at Cumberland and Westmorland, Brentwood, Netherne, Lancaster, and Cheddleton. The number of post-mortem examinations held in county and borough mental hospitals was 5404, being 68·8 per cent. of the deaths. The percentage varied from 90 or more at some hospitals to 17 and 15 at others. The total expenditure on county and borough mental hospitals, during the year ending March 31st, 1930, amounted to £8,148,752, of which £7,028,845 represented maintenance. This was an increase of over £90,000 in the cost of maintenance and over £80,000 in the cost of building and repairs, compared with the preceding financial year. At the beginning of 1930 there were 1209 patients under treatment for tuberculosis, a proportion of 10·3 per 1000 of the total number resident. The highest incidence is in Notts County, Middlesbrough, Cumberland, Derby County, Cotford, and Northumberland, obviously to some extent a geographical distribution. The death-rate from this disease has been reduced to 6·3 per 1000 patients resident. Suitable quarters for tuberculous patients are being provided in an increasing number of mental hospitals, but there are still some for whom appropriate accommodation is inadequate.

There were 106 cases of typhoid and paratyphoid fevers, a decrease of 14 on the previous year. Two epidemics were traced to a polluted water-supply. The number of cases of dysentery—254—was reduced by nearly a third from the previous year. A great deal of time and work has been devoted to the discovery of the source of intestinal infections, particularly carriers. One instructive case was found to carry not only typhoid but also dysentery and another diarrhœal disease. Attention has also been directed to new admissions who may introduce infection. An increasing number of hospitals practice protective inoculation. There was less influenza last year than the year before, and the fall in pulmonary tuberculosis was coincident.

Mental Deficiency.

The progress on the mental deficiency side has been more satisfactory than the figures might suggest, and the Board records with approval a marked awakening of local authorities to the wisdom and necessity of carrying out their duties in this branch. At the present time 53 county councils and 61 county boroughs are seriously and actively considering some scheme for residential provision, while only 10 appear to have taken little or no action. Three new institutions were opened during the year and 1255 additional beds provided. If schemes recently submitted materialise, some 10,000 extra beds will have been provided in about five years' time, and the Board estimates that at this rate it will be possible, with active, continuous, and prolonged effort, to meet the demand for the most urgent of the young trainable and employable cases in about 15 or 20 years. The committee, under the chairmanship of Mr. Walter Hedley, K.C., has now presented its report on economy in the provision and maintenance of homes for the defective. It did not succeed in cutting the requirements of the Board much finer. The Board realises that the cost of construction is of real importance in the development of colony policy, and is glad to note that there has been a steady fall; the cost may now be taken at about £300 a bed, this including all the administrative buildings of a complete colony.

The Board regrets that occupation and industrial centres are not being developed more rapidly to help parents who are both willing and able to keep their mentally defective children at home but cannot provide them with suitable occupation and training. It has been proved repeatedly that the initial difficulties in the establishment of day centres can be overcome and that these centres meet the needs of the situation in an inexpensive and efficient manner. The Board thinks that it is not yet generally recognised that all defectives—except the lowest grade idiots—benefit from training, and that without it even the best behaved are apt to degenerate.

Another important provision in which there has been no increase during the year is that of hostels for defective boys and girls whose training has fitted them for work outside an institution. The hostel forms an invaluable link between the institution and the community and saves the advancing defective many unnecessary disasters.

The increase in the number of defectives ascertained by local authorities has been maintained and the ratio per 1000 is now 2·17 as compared with 1·81 a year ago. The report, as usual, lists areas in which ascertainment seems to be inadequate and gives some illustrations of the terrible results of failure to ascertain. It reviews the methods of community care afforded by the Mental Deficiency Acts and the extent to which they are being carried out by local authorities. Once again the problem of marriage and sterilisation comes up for discussion, and once again the Board strongly recommends prohibition of marriage and feels that there is not as yet sufficient knowledge to justify even the most cautious legislation for sterilisation.

The Board urges again the separation of defectives from psychotics, but the shortage of provision for the former means that mental hospitals still have a large number of defectives in residence, an arrangement which is essentially bad for everybody concerned. On Jan. 1st, 1931, there were 55,064 mental defectives under care, 2120 of them under guardianship or notified.

The report concludes with a brief review of research work in mental hospitals; this will be dealt with more fully in the second part of the report, to be published later in the year.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 27TH, 1931.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 48; scarlet fever, 1427; diphtheria, 882; enteric fever, 31; pneumonia, 552; puerperal fever, 49; puerperal pyrexia, 99; cerebro-spinal fever, 40; acute poliomyelitis, 4; acute polio-encephalitis, 1; encephalitis lethargica, 10; continued fever, 1; dysentery, 21; ophthalmia neonatorum, 110. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on June 30th–July 1st was as follows: Small-pox, 124 under treatment, 1 under observation (last week 138 and 2 respectively); scarlet fever, 1112; diphtheria, 1421; enteric fever, 13; measles, 137; whooping-cough, 436; puerperal fever 36 (plus 8 babies); encephalitis lethargica, 206; poliomyelitis, 2; "other diseases," 152. At St. Margaret's Hospital there were 11 babies (plus 6 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 1 (1) from enteric fever, 27 (0) from measles, 3 (1) from scarlet fever, 21 (7) from whooping-cough, 18 (2) from diphtheria, 39 (13) from diarrhœa and enteritis under two years, and 24 (3) from influenza. The figures in parentheses are those for London itself.

Small-pox was mentioned as the cause of death for the month of May in a case assigned to Coalville U.D., Leicestershire. Three deaths from meningococcal meningitis were reported in London, 2 from 15–25 years, 1 from 25–35. Eight deaths from measles occurred in Sunderland, 4 in South Shields, 3 in Birmingham. Birmingham reported 3 deaths from whooping-cough.

The number of stillbirths notified during the week was 275 (corresponding to a rate of 40 per 1000 births), including 37 in London.

CENTENARY OF THE LEEDS SCHOOL OF MEDICINE.

THE centenary of the Leeds School of Medicine was impressively and pleasantly celebrated on July 1st. The growth of what is now the Medical Faculty of the University of Leeds from the Medical School founded in 1831 makes a stimulating story. The school was united with the Yorkshire College in 1884. By this act of union the Yorkshire College was enabled to apply for admission to the Federal Victoria University and became one of its constituent colleges in 1888. In 1904 the University of Leeds became an independent University on the disruption of the Victoria University. From its earliest beginnings, when it found accommodation in a few back rooms in North-street, the progress of the medical school has been steady and encouraging. From 1834 to 1864 the work was carried on in a house in East Parade (Fig. 1) which is now converted into offices. In 1864 Sir James Paget opened the buildings in Park-street, where several men who are still in active work took part in the teaching. These buildings were planned by Mr. George Corson, under the guidance, so far as their requirements were concerned, of the members of the teaching staff. In those days, however, little more was deemed necessary than a dissecting room, a lecture theatre, and very limited laboratory accommodation. In 1894 a long cherished wish was realised, and the present building in Thoresby-place was opened by the King and Queen, at that time the Duke and Duchess of York. Excellent accommodation was secured for the anatomical department; what was deemed adequate for physiology and pathology was provided, and the facilities for the teaching of the other subjects were greatly increased. The buildings were erected according to plans drawn up by Mr. W. H. Thorpe. With this

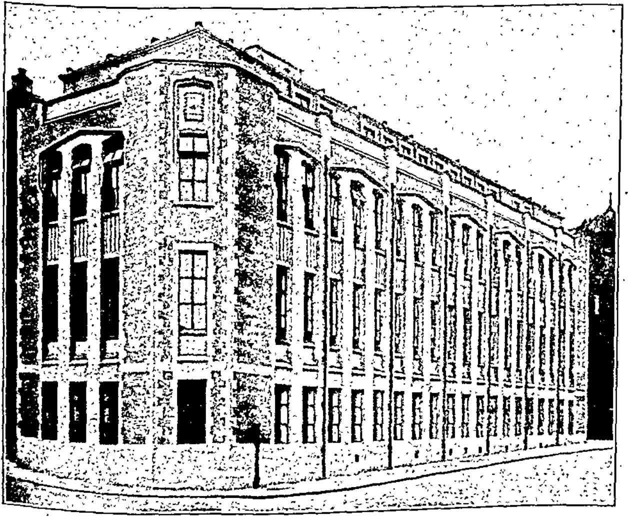
great advance in the school there must always be associated the honoured name of Thomas Scattergood, who was for many years Dean of the school and of the medical department of the Yorkshire College. He it was who determined in his mind the site, who impressed the authorities with its manifest advantages, who succeeded in inducing the college to acquire the land, and who, ably seconded by Prof. Birch and in a lesser degree by others, watched every step in the preparation of the plans and in the actual carrying out of the work. Scattergood, by his great personality, developed in others something of his own enthusiasm. The building occupied three sides of a quadrangle, and though little has required to be altered in the structure, extensions to improve the accommodation for physiology and pathology have been found necessary. The first requirement has been met by the completion of the fourth side of the quadrangle, and this part of the building has been planned by Mr. J. C. Procter, advised by Prof. McSwiney (Fig. 2). The large new block which is being put up in the immediate vicinity of the main building will give ample accommodation for an Institute of Pathology. It is impossible to think of the Leeds School of Medicine apart from the School of Dentistry, or from the General Infirmary, and other charitable institutions of the city. The position of the school buildings in relation to some of the associated institutions is shown in Fig. 3.

The main event in the celebrations was the congregation of the university over which the Chancellor, the Duke of Devonshire, presided. About 50 delegates from the other universities of the country and of other teaching bodies and institutions, were first received by the Chancellor, and addresses of welcome were then given by him and by the Vice-Chancellor, Sir James Baillie. Replies were made by Sir Humphry Rolleston and by Major-General Hime, R.A.M.C., a former pupil of the school. Honorary degrees were then conferred upon Dr. Hawkyard, who occupies the position of Lord Mayor, on Dr. Jane Walker, Dr. A. G. Barrs, Sir John Bland-Sutton, Lord Dawson of Penn, Sir Walter Morley Fletcher, Sir Gowland Hopkins, and Sir George Newman.

On the evening before the formal ceremony a dinner was given by the past students of the school, at which most of the delegates were present. The chairman was Lord Moynihan, who proposed the toast of the guests in felicitous terms; Prof. Arthur Hall, of Sheffield, replied. Most of those present went on to a reception which was given by the Lord

FIG. 2.



The new wing, opened in 1930, of the present School which dates from 1831.

Mayor at the Art Gallery. On the same day as the congregation was held, the Leeds and West Riding Medico-Chirurgical Society, of which this year the Lord Mayor happens to be the president, gave a luncheon to the delegates. Speeches were made by the President, by the Duke of Devonshire, by Prof. Dobson, and by Sir George Newman. On the same afternoon receptions were held at the School of Medicine and at the General Infirmary, and a long, interesting, if somewhat full, day was brought to a close by the university dinner, presided over by Colonel Tetley, the pro-Chancellor, followed by a ball.

The celebrations have done much to emphasise the unity of the university, of which indeed the school is the oldest part. Its old names need not even now be laid aside, and as the Medical School of the University of Leeds its continued development and prosperity is assured.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

VISIT OF DR. ARIËNS KAPPERS.

Dr. C. U. Ariëns Kappers, Director of the Central Institute of Brain Research at Amsterdam, visited Dublin last week to receive the Degree of Doctor in Science *honoris causa* from the University of Dublin. During his visit he gave three lectures, which were open to all medical men and students of medicine or science. On July 2nd he lectured to the Royal Academy of Medicine in Ireland on the Structure of the Brain in Prehistoric and Historic Races. On the 4th he lectured to a meeting of the British Neurological Surgeons on the Phylogeny of the Glial and Meningeal Tissues and the Cerebro-Spinal Fluid Cavities, and to the Royal Medico-Psychological Association on the Function of the Layers of the Cerebral Cortex. Despite the abstruse nature of his topics, Dr. Kappers's gifts as a lecturer and his admirable command of the English tongue rendered his discourses intensely interesting to his audiences.

HONORARY DEGREES AT DUBLIN UNIVERSITY.

In addition to that conferred on Dr. Kappers, two other honorary degrees of interest to the medical profession were conferred last week at the Summer Commencements of Dublin University. The degree of Doctor in Medicine was conferred on Sir John Rose Bradford, F.R.S., late President of the Royal College of Physicians of London. In presenting Sir John, the Public Orator, Sir Robert Tate, Fellow of Trinity College, Dublin, drew attention to his pioneer work on the physiology of renal secretion, and his applications of his findings to clinical medicine. A similar degree was conferred on Major-General Sir Foster Reuss Newland, who was himself educated at Dublin University. The Public Orator drew attention to Sir Foster's distinguished services in the Great War.

DISCUSSION OF A DUBLIN HOSPITAL IN THE SENATE.

Last week Senator Sir John Keane moved in the Senate of the Irish Free State that the Dublin Skin and Cancer Hospital should be included in the Sweepstake Scheme. The proposal led to a warm debate, in which the proposal was opposed by two medical men who are senators, Mr. O. St. Gogarty and Sir Edward Coey Bigger. The Minister for Justice gave his opinion, as reported in the daily press, that he was satisfied that the Cancer Hospital was not a voluntary institution. The accounts showed that the patients paid considerably more than the whole expenditure of the hospital. He was convinced that the Hospitals' Committee was right in refusing the application to include that hospital in the sweep. Sir John Keane withdrew his proposal.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

Surg. Vice Admiral Sir Arthur Gaskell, K.H.S., has been placed on the Retd. List.

Surg. Rear Admiral R. St. G. S. Bond to be Surg. Vice Admiral.

Surg. Capt. H. R. H. Denny to be Surg. Rear Admiral.

Surg. Comdrs. Cyril V. Griffiths and Frank L. Smith to be Surg. Capts.

Surg. Lt. J. G. Maguire to be Surg. Lt.-Comdr.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lt.-Comdr. R. Hall to be Surg. Comdr.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. C. H. Turner, having attained the age for compulsory retirement, is placed on retd. pay.

Lt.-Col. C. R. M. Morris retires on retd. pay on account of ill-health.

Majs. T. J. Mitchell and R. C. Priest to be Bt. Lt.-Cols.

Maj. (temp. Lt.-Col.) W. B. Purdon to be Lt.-Col.

Maj. F. Casement to be temp. Lt.-Col.

Lt. T. E. Moles to be Capt.

Lt. J. C. Gilroy to be Capt., and remains secd.

D. K. Weston is granted a temp. commn. in the rank of Lt.

TERRITORIAL ARMY.

Lts. R. S. Taylor and C. M. Willcox to be Capts.

J. G. McCrie (late Cadet Serjt., G. Watson's Coll. Contgt., Jun. Div., O.T.C.) to be Lt.

R. H. Ballard to be Lt.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Capt. T. H. Sansome, from Active List, to be Capt.

INDIAN MEDICAL SERVICE.

Lt.-Col. H. H. Thorburn to be Bt. Col.

Capt. J. R. Katariya to be Maj.

Lt. J. P. J. Little to be Capt.

Lt. (T.C.) N. L. Sah to be Capt. (T.C.).

ROYAL AIR FORCE.

Air Comdr. J. McIntyre to be Air Vice-Marshall.

Squad. Leader J. Rothwell and E. W. Craig to be Wing Comdrs.

COLONIAL MEDICAL SERVICE.

Dr. D. O. Peters has been appointed Medical Officer, Nigeria; Dr. E. J. Blackaby, District Medical Officer, Cyprus, has been promoted Medical Officer in the East African Medical Service, Nyassaland, and Dr. F. Keyt, Provincial Surgeon, Western Province of Ceylon, has been promoted to Medical Superintendent there; while Miss M. M. McDowall, Lady Medical Officer, Sierra Leone, has been made Lady Medical Officer, Gold Coast. Dr. L. A. Prins, Assistant Director of Medical Services in Ceylon, has been promoted to Deputy Director of Medical and Sanitary Services.

COMMISSIONS IN ROYAL ARMY MEDICAL CORPS.

Twenty-five permanent commissions in the Royal Army Medical Corps are offered to registered medical practitioners, under 28 years of age. There will be no entrance examination, but candidates will be required to present themselves in London for interview and medical examination. At the same time, a certain number of temporary commissions under similar conditions as regards age and qualifications will also be offered. Applications should reach the War Office not later than July 20th. All information as to conditions of service and emoluments may be obtained from the Under-Secretary of State, The War Office (A.M.D.1), Whitehall, London, S.W.1.

BRISTOL GENERAL HOSPITAL: ANNUAL REPORT.—In 1930 the new in-patients numbered 4387, a fractional reduction upon the preceding year; the out-patients were 30,751, also a small diminution. The average stay was 19·33 days, and the total cost per head £8 13*s.* 4*d.* The net deficiency on the year was £9629, and the bank overdraft was £21,159. The committee express their "profound concern" at the large number of patients awaiting admission.

CORRESPONDENCE

SUCCESSFUL MEDICAL SOCIETIES.

"A."—FOUR DISTINCT GROUPS.

To the Editor of THE LANCET.

SIR,—At no time in the history of medical science in this country have medical societies been more successful or more prosperous than at present. The reason is not far to seek if one considers what are the prime motives of these societies. They can be divided into four big groups.

(1) The *Specialist Society.*—In this category come the sections of the Royal Society of Medicine, the Association of Physicians, the Biochemical Society, and kindred organisations. Their object is to discuss theories and present new facts to those who are most able to criticise. The very spirit of criticism and scientific enterprise which is the essential atmosphere of such a body is necessary for keeping alive the fire of enthusiasm which all research workers need. These bodies often publish proceedings which form a useful platform from which to address a wider specialist audience, and act as a record of work done in special branches. Such groups must avoid the tendency to become too narrow or to be monopolised by a few individuals. When very specialised they act as an international medium, and their smaller use in a little sphere is compensated by their wider use in a larger one.

(2) The *General Medical Society.*—Here, particularly in the smaller towns, the membership consists largely of general practitioners, with two or three men representing respectively the various specialties. Here, too, a lecturer may be asked to read a paper on a given subject which is afterwards discussed by the general body. Clearly in this group the objects aimed at will be different from the first. The knowledge propounded will usually be far more proved, for the audience will be less able to criticise the more debatable aspects. If a paper is read by a specialist there will be a general unwillingness to cross swords with him. The society serves rather as a forum before which the general practitioner can receive a résumé of recent work, and as a stimulus to his own reading. This group brings men and women together socially, gives opportunities for good fellowship, and provides an efficient medium for concerted action in measures affecting the local corps medical. It also can act as a disciplinary body.

(3) The *Mixed Society* consists of doctors and laymen who have some common point of interest. An excellent example is the Medico-Legal Society, of which the members are either medical men, barristers, solicitors, chemists or others interested in forensic medicine. The chairman is alternately a doctor and a lawyer. Discussions here are very different from those heard at pure medical meetings. The criticising ear of another profession, and the need for an exact explanation of technical terms, induces a real clearness in the speaker's mind, while the medical focus is widened. Valuable friendships are formed in such a society, and it is not too much to say that the public health and criminal laws are greatly influenced by discussions at bodies of this kind where law-makers and experts meet in a spirit of camaraderie. Such a body has important repercussions in bringing out the medical snags of existing legislation, such as that on poisonous drugs, the punishment of juvenile delinquents, or the place of psychology in the criminal code.

(4) The *Hospital Society.*—In a fourth group are societies that have gathered round a hospital or centre—e.g., the West London Medico-Chirurgical Society, which was an offshoot of the West London Hospital, the Chelsea Clinical Society, and others. Attendance at meetings of these societies is small for many reasons. The practitioner finds the time of meeting clashes with his evening surgery, and naturally does not always wish to go to a medical meeting on his free evening. The consultant has his own society in town. Various expedients have been tried, of which the two most successful are dinner meetings and cinema films. A dinner meeting, if there is a good opener, will often attract 40 or 50 members. In organising a discussion good stage-management is needed. On a subject such as cholecystitis a physician may open who will be followed by a surgeon and pathologist, so that a complete picture of the disease is placed before the audience in its newest relationships.

As Dr. Raymond Crawfurd says, one of the important functions of a medical society is to provide a medium for the conveyance of fresh knowledge from the centre to the periphery. Apart from actual meetings, societies can do this in two ways: first, by a library service; and secondly, by publishing transactions. A magnificently organised library such as that of the Royal Society of Medicine does invaluable service. The ordinary worker has not the time to look up the many references needed for writing a scientific article, nor is he able to buy the books or periodicals required to keep abreast of modern knowledge in a specialty. This service can only be done by a well-supported medical society.

In clinical medicine the medical society is a stage for securing advice in a difficult case or enlarging clinical experience by seeing cases well worked out by others. The duty of presenting a case imposes on the practitioner a stimulating piece of work. Osler often used to tell his students that there was nothing that clarified one's knowledge so much as the writing of a short article. The general practitioner has a rich harvest of clinical material, and medical societies offer a ready medium for the projection of this knowledge. One of the most promising roads of advance in medicine lies along the way of clinical work carefully observed, annotated, and accurately presented. In furthering this work medical societies can do yeoman service.

I am, Sir, yours faithfully,

June 20th, 1931. A RESEARCH FELLOW.

"B."—THE PART PLAYED BY TRADITION.

To the Editor of THE LANCET.

SIR,—The ideal medical society is a subject which appeals very much to me; I am quite sure that tradition plays an enormous part, while Dr. Crawfurd is right when he says it must be run by men who are still young. The best medical societies I know are those of Guy's and Edinburgh. The London Hospital Medical Society, though younger, follows pretty closely in order of excellence. Now the reason for this excellence, I am certain, is the traditional interest taken by students in the society, at meetings of which there is much more active discussion from students, house officers, registrars, and members of the staff than is usually heard. The meetings which are successful at the Royal Society of Medicine are those where the work of some great contributor to medical knowledge is discussed, preferably by himself.

For example, the world-wide interest in B C G will attract people, and rightly so, to hear Calmette. So that the first essential in the ideal medical society is never to let Tom, Dick, or Harry invite himself to give a paper, but to choose somebody who is actively engaged on a subject which is bound to interest a large audience.

Societies, however, are apt to make the mistake of inviting a foreigner to give an address without having made sure as to the quality of his English. This can sometimes be remedied by the right sort of interpreter. At the thirteenth International Physiological Congress, which can be taken as a medical society for the purposes of this discussion, Pavlov addressed a packed meeting in Russian. At the opposite end of the platform was his distinguished pupil Anrep, who took up sentence by sentence and translated it. Nevertheless, the interest was in what Pavlov himself said. In our ideal medical society we would choose the enthusiastic English student of the great foreign master to interpret for him in this way. After all, the people came to hear Pavlov, and were delighted to *see* him speak, since hearing conveyed nothing.

Another point of the greatest importance is to explain to a man, even though he be a lecturer in a medical school, that his words will go for nothing unless he speaks up. It amazes me how many men cannot make themselves heard in the back row. My short experience tells me that every lecturer should expend time and trouble in making sure that his illustrations are bold and visible, so to speak, beyond the back row. A man will have the impudence to place on the epidiascope screen a closely typed foolscap page; the result is that he himself on the platform is the only man who can read it. What should be done is that his information should be condensed and every letter marked out boldly with India ink upon engineers' linen. It should be arranged in a square to fit in to a lantern slide. All charts, tables, and historical discussions should be put out in the same way.

In regard to clinical evenings, the greatest source of ill-success is to have too many cases. What one requires is to have a small number of cases so well selected that the discussion can hold an audience whose interests are wide apart. Furthermore, after the patient is wheeled out the demonstrator should address the audience in a bold voice, using illustrations and photographs prepared in accordance with the foregoing rules.

I am, Sir, yours faithfully,

June 22nd, 1931. MEDICAL CONSULTANT.

"C."—COLLECTIVE EXPRESSION OF LOCAL PRACTITIONERS.

To the Editor of THE LANCET.

SIR,—Local medical societies, that is to say, societies whose primary function is the consolidation of local unity and fellowship, are not so common as they might be. The completion, therefore, of the first year of its existence by the Paddington Medical Society is deserving of mention. Its achievements may prove a useful example to those seeking the formation of similar societies elsewhere.

In addition to clinical objects this society defines amongst its aims the promotion of the efficiency and independence of practitioners, and its record during the past year goes some way to justify the pretension. Its syllabus has included an extensive range of material in the fields of public health, medical jurisprudence, hospital and consultant liaison, the administration and extension of public services and their encroachments on private practice, the present and future administration of the National Insurance Acts, and the function of medical journalism. This may seem a somewhat wide horizon for a local society. But the aim, apparently successful, has been to effect a combination of subject and speaker so as to ensure useful as well as interesting references to the problems of actual practice.

Two features of this society's work deserve special mention. These are the production of a report on national health insurance practice, and a scheme for the reduction of infant mortality in Paddington. The report is the work of members who are themselves insurance practitioners, and it reviews, critically and constructively, the principles and the administration of the Acts since their inception.[1] The inauguration of a scheme for general practitioner treatment of infants in Paddington whose parents are unable to afford the paid services of a doctor has been brought about by voluntary liaison between medical and other officers of public services, private practitioners, and interested lay sympathisers in Paddington. Its importance lies partly in the absence of official municipal or State control, and of any element of compulsion. Its financial administration has been linked up with that of the London Public Medical Service, and its operation is open to any practitioner in Paddington.

The Paddington society deserves congratulation on the completion of work which has been not only attractive and interesting to its own members, but, though modestly conceived in the first place for the purposes of local discussion, has attracted attention outside the borough.

I am, Sir, yours faithfully,

June 20th, 1931. A GENERAL PRACTITIONER.

TREATMENT OF CEREBRO-SPINAL FEVER.

To the Editor of THE LANCET.

SIR,—In your issue of June 20th (p. 1373) L. H. Copping asks for other observations on the treatment he describes. During the war I had charge of the military cerebro-spinal fever cases in the Isle of Wight, and generally injected the cerebrospinal fluid intramuscularly, in addition to intrathecal injections of antimeningococcal serum. It was, I think, a valuable aid to recovery. In several pleuritic effusions I had injected the fluid in the same way, and this gave me the idea.

I have also used a somewhat similar treatment in a severe case of pemphigus.

The patient, a boy 2 years old, had bullæ profusely scattered over the body and limbs and seemed very ill. The mother stated that at the age of 4 months he had had a very similar attack and nearly died, and that he had had some milder recurrences at intervals since. Fluid was drawn from the blebs, and about 2 c.cm. was injected intramuscularly. The condition rapidly cleared up and the boy was free from symptoms until two years later, when he had another attack and the treatment was repeated. This was done four times in all, at varying intervals of a year or two, the symptoms being rather less severe each time. He is now ten years old, and has been practically free for two years. There was no syphilitic history.

The mother is convinced of the value of the injections. The blebs dried up rapidly after injection and fresh crops ceased to appear.

I am, Sir, yours faithfully,

L. P. GIBSON, M.R.C.S., L.R.C.P.

Cowes, Isle of Wight, July 4th, 1931.

ACUTE RHEUMATISM FOLLOWING TONSILLITIS.

To the Editor of THE LANCET.

SIR,—There are several points in Dr. E. C. Warner's letter which require comment. When at the first annual meeting of the British Pædiatric Association, held at Windermere in May, 1928, I first discussed in a paper the "silent period" between nasopharyngeal infection and subsequent rheumatic relapses,[1] the theory received some criticism. Dr. Campbell and Dr. Warner's valuable studies published in your columns in 1930, and Dr. Sheldon's recent article, gave me, therefore, some satisfaction in confirming my original thesis. I cannot agree, however, with Dr. Warner that these acute relapses of rheumatism "can occur after any illness liable to produce a state of lowered resistance in the child." Surely there must be a more definite explanation than this, especially as a similar "silent period" is the rule when rheumatism follows the exanthemata that Dr. Warner has quoted. It is significant that, with the exception of chicken-pox, all the acute infectious fevers mentioned by him as giving rise to rheumatic complications are closely associated with streptococci in the throat. This, to my mind, is the important common factor between them and acute tonsillitis in the ætiology of subsequent rheumatism. Dr. Poynton and I tried to express this in our recent book on rheumatism when we said (p. 105) that "the first symptoms in a certain proportion (of rheumatic children) will be found to date back to a definite illness. Scarlet fever is the best known example, but the commencement of rheumatism has also been traced to other infections in which the streptococcus is much in evidence, such as measles, influenza and diphtheria . . ."

Dr. Warner appears to have misread Dr. Sheldon's argument about the non-infectiousness of rheumatism. I understood him to imply that rheumatism per se is not *infectious* to other patients, although the preceding throat infection might be. Much has been written about contagion in rheumatism, and Dr. Poynton and I took some pains in our book to refute this supposition. Nobody with any knowledge of rheumatism in children could dismiss peremptorily an *infective* element from the disease, although the exact bacterial pathogenesis is perhaps still not entirely clear. Here I am in agreement with Dr. Warner, but would hesitate to accept his simile between the valvular vegetations in rheumatism and subacute bacterial endocarditis as in any way proof of his contention. At this juncture, however, I do not wish to draw that red herring into your columns.—I am, Sir, yours faithfully,

BERNARD SCHLESINGER.

Portland-place, W., July 4th, 1931.

To the Editor of THE LANCET.

SIR,—Dr. Warner regards one of my remarks as "an unwarranted conclusion." This is because he has misunderstood my use of the word *infectious*, and I should therefore be glad if you would allow me to correct the wrong impression which my sentence has created.

Various authors have pointed out that acute rheumatism may occur in epidemics. In my paper evidence was advanced to show that acute rheumatic relapses were often preceded at a definite interval by sore throats, and one of the points I wished to bring forward was that the spread of rheumatism from case to case was carried out through the medium of the preliminary sore throat. In order to illustrate this point I compared the rheumatic reaction with post-diphtheritic paralysis. Everyone knows that epidemics of diphtheritic sore throat may occur, but surely no one imagines that post-diphtheritic paralysis can be conveyed from case to case. Using *infectious* in the sense of *communicability of disease*, I wrote "the rheumatic reaction whether arthritic or cardiac, has no more claim to be considered infectious than has, for example, post-diphtheritic paralysis." I was not concerned with the question of whether the rheumatic reaction was *infective*, using infective in the sense of "invasion of the tissues by pathogenic organisms." To have said that the rheumatic reaction was not the outcome of an infection by organisms would indeed have been an unwarranted conclusion.

I am, Sir, yours faithfully,

London, W., July 7th, 1931. WILFRID SHELDON.

STATE CONTROL OF THERAPEUTIC SUBSTANCES.

To the Editor of THE LANCET.

SIR,—In your report (June 27th, p. 1401) of my remarks on Dr. Hartley's paper unfortunately one word has dropped out. The final sentence should read, "It was hoped to make a Schick toxin which would stand *hot-room* temperature for several days." The point is a not unimportant one. The original Schick toxin used some years ago with a phenol diluent was very unstable. By the use of boric-borate-buffer (Glenny and Pope) there has been available for several years, and in clinical use, toxin diluted with buffer solution which is stable for many weeks. Recently Bunney (U.S.A.) used 2 per cent. peptone solution as a diluent. We find some difficulties with this particular dilution, and A. T. Glenny has made a variant. He finds that 1–1000 peptone dilution with buffer solution provides Schick toxin which is stable in the hot room for at least a week, and at ordinary room temperature for months. This has been tried clinically and appears to be satisfactory.

I am, Sir, yours faithfully,

R. A. O'BRIEN.

The Wellcome Physiological Research Laboratories,
Beckenham, Kent, July 1st, 1931.

MORTALITY AFTER PROSTATE OPERATIONS.

To the Editor of THE LANCET.

SIR,—I was gratified to see that my small article in your issue of June 13th brought letters from both Mr. Everidge and Mr. Page. At the same time I feel one or two points require further attention.

In the first place, may I say that the object of the article was to bring to notice the importance of the matter, and it was only a preliminary report of research work which I have still under investigation. In the second place, I am well aware that the blood-urea is altered by many conditions other than the effect of ether. It is so affected by gas and oxygen anæsthesia. I simply tried to suggest that this was not to the same extent as when ether was employed, and I think that this is borne out by the Table I gave of a series of cases of general surgery. I could have provided evidence to show that with spinal anæsthesia there was not the same post-operative rise. As to the mortality-rate after prostate operations in "a hospital," the figure was taken from the only material I had available at the time, and was simply used as an illustration to substantiate my view as to this being too high. I have since learned that the average mortality-rate in that hospital over a number of years is considerably less.

---

[1] Arch. Dis. Child., 1928, iii., 176.

Finally, I would like to add that the experience of Mr. Page—whose skill in spinal anæsthesia I witnessed 14 years ago—rather supports the view suggested in my article.—I am, Sir, yours faithfully,

Liverpool, July 6th, 1931. R. J. MINNITT.

AUDIOMETRY AND AUDIOGRAPHY.

To the Editor of THE LANCET.

SIR,—In the report of the discussion on audiometry and audiography in the Otological Section of the Royal Society of Medicine in your issue of July 4th, p. 20, I am credited with referring to a paper I read some years ago (at the International Otological Congress at Boston, U.S.A., in August, 1912) showing a method of audiometry by tuning-forks, correcting the time error by a logarithmic scale, and reducing it to true loss of hearing power. That, however, accounted only for duration, not for the dying away of the vibrations. This latter sentence should apply only to the method of audiometry devised by Hartmann, which recorded simply the percentage loss of duration of hearing for the tuning-forks. The application of the logarithmic scale *did* take into account the dying-away of the vibrations and reduced the percentage loss of duration of hearing to the percentage loss of hearing power.

The methods of testing and of logarithmic correction will be found in detail in the *Journal of Laryngology* (June, 1929). I have a few reprints at the disposal of any who are interested in the subject.

I am, Sir, yours faithfully,

London, July 7th, 1931. JAMES DUNDAS-GRANT.

TUBERCLE BACILLI IN CREAM.

To the Editor of THE LANCET.

SIR,—Much attention has been focused on the need of a pure-milk supply in England—particularly in relation to tuberculosis. Little mention has been made of the possibility of cream and butter containing tubercle bacilli. Can you enlighten me on the subject? In India, in military dairies, it is customary for milk to be pasteurised before being made into cream and butter, in order to prevent the possibility of the spread of typhoid by these foodstuffs.

I am, Sir, yours faithfully,

G. FAWSITT TAYLOR,
Captain, Indian Medical Service.

King's College Hospital, July 4th, 1931.

PUBLIC HEALTH SERVICES

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are 1930 statistics of five county boroughs:—

Name of district and estimated (R.-G.) mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Infant and neonatal mortality.	Young child (1–5 yr.) mortality.	Maternal mortality in childbirth.
Coventry (173,240)*	13·9	9·6	0·94	1·16	1·4	1·8	57/30	21	7·0
Reading (97,050)†	14·4	11·4	1·06	1·53	1·7	1·5	55/39	9	2·1
Bootle (84,970)*	21·1	11·1	1·27	1·00	1·9	1·4	79/26	36	3·3
West Bromwich (80,840)†	20·7	11·4	0·84	1·30	2·2	1·9	66/35	35	2·4
Eastbourne (59,000)‡	11·3	11·3	0·63	1·76	1·0	2·4	40/24	10	6·0

Registered stillbirths per 100 live births:—Coventry 4·9, Reading 3·3, Bootle 4·7, West Bromwich 4·0.

* Local estimate. † R.-G. estimate for 1929. ‡ R.-G. estimate for 1929 was 58,570.

Coventry.

Dr. A. Massey refers to 1930 as an historic year, as during it the Local Government Act, 1929, began to operate from April 1st and the Housing Act, 1930, was born, whilst the Mental Treatment Act was passed and came into operation on Jan. 1st, 1931. The chief change under the first Act was that the former poor-law hospital became the Gulson-road Municipal Hospital. It contains 301 beds and the new nurses' home begun by the guardians was officially opened on April 1st, 1931. At present it contains a more or less stationary population of 100 chronic cases, who are suited to a simple institution rather than to a well-equipped hospital, and the need for the early removal of these cases is evident. The housing position in Coventry is peculiarly difficult owing to the rapid increase in population pari passu with the virile growth of local industry. The five year programme includes a clearance of five small areas (150 houses with 750 inhabitants), the demolition of 75 unfit houses occupied by 375 persons, and the renovation of 600 unfit houses. It is also expected that during this period most of the 649 munition hutments owned by the council and 377 privately owned hostels of a similar type will be demolished. During the year the Coventry House Improvement Society has been formed and its first operation has been to acquire and recondition 14 houses at a cost of £900.

The Mental Treatment Act virtually establishes a preventive side to psychological medicine by providing for "voluntary" and "temporary" patients. A mental out-patient clinic is already in existence, conducted by the medical superintendent of Hatton Mental Hospital. In the matter of provision for mental deficiency accommodation has been found in outside institutions for high-grade defectives. The guardians had acquired the Exhall estate, which now comprises 144½ acres, and a scheme is on foot to make initial accommodation for 40 male low-grade defectives and to increase the accommodation gradually to 400 beds. During the year complete coördination was effected between voluntary and municipal child welfare centres. The public health committee now supplies the medical and nursing services at the voluntary centres. Plans have been prepared for a new isolation hospital of 152 beds with a view to extension ultimately to 236 beds. All the preliminary details of the public abattoir scheme have been completed and a loan sanctioned for £83,210. Building will begin during the current year.

In June a representative committee was appointed by the Warwickshire and Coventry tuberculosis committees to consider and report on the desirability of forming a joint tuberculosis colony similar to Papworth. The committee was still at work at the year end. Diphtheria was the only infectious disease which occasioned serious concern during the year.

There were 484 cases notified and 40 deaths—a case-fatality of 8·3 per cent. During the year 734 school-children were immunised.

Reading.

Dr. H. J. Milligan reports that the primary step under the Local Government Act was the constitution of the hospital portion of Battle Infirmary (formerly poor-law) as Battle Hospital and the delegation of its management to the health committee. Under a progressive board of guardians this hospital during the last ten years has been brought thoroughly up to date. The beds number 279, and the hospital is well-equipped for general medicine, surgery, midwifery, and diseases of women. Under the new Act the relieving officer no longer acts as a necessary medium between the sick person and a bed in the hospital, but the medical superintendent is in direct touch with outside practitioners for the admission of their patients. The mental deficiency committee has in hand a comprehensive scheme to provide for the accommodation of mental defectives.

An extensive site has been procured for the housing programme of the next five years. There are about 600 houses which fall below a reasonable standard of fitness and of these 238 have been scheduled for demolition. It is also proposed to deal with a series of clearance areas and to erect 2000 additional houses on the Whitley estate. By-laws are needed for houses let in lodgings, chiefly houses originally used by single families and now let to several tenants. As examples of the exorbitant rents obtained, Dr. Milligan mentions a large house holding 11 separate families who pay a total weekly rent of £7 8s. 6d.

A small explosive outbreak of glandular fever affecting nine persons occurred in one of the university hostels in May. The principal features were fever for from two to eight weeks, a rash similar to typhoid, and enlargement of the glands of the neck and scalp. All the patients recovered without ill-effect. One case of undulant fever occurred; the patient made a good recovery. Dr. Milligan mentions that the neonatal mortality-rate was much higher than the average of recent years, but he has no satisfactory explanation to suggest. During the year, 34 milk samples were examined for tubercle and four gave a positive result. During the past 11 years out of 282 milk samples examined 31, or more than 10 per cent., have contained tubercle bacilli. For the disposal of refuse "controlled tipping" has been adopted. The process has been closely followed during the year and no complaints of flies, rats, or offensive smells have been received.

Bootle.

As the institutions of the West Derby Union which deal with the sick and able-bodied poor are outside the borough, an agreement has been made with the Liverpool City Council that for a period of ten years Bootle shall be at liberty to send these patients to the Liverpool Public Assistance Committee's institutions. It is hoped to provide for the maternity cases at present confined in Liverpool Public Assistance institutions in an enlarged Bootle maternity home. Domiciliary (poor-law) medical attendance is now controlled by the Public Assistance Committee acting through Dr. F. T. H. Wood, the medical officer of health, and the two district medical officers are empowered to use the services of the nurses of the Bootle Association for patients treated at their own homes.

Since 1920, 1665 municipal houses have been built; the renovation of 1200 houses during the next five years is contemplated. A beginning has been made with the postnatal supervision of mothers; 747 new cases attended the antenatal clinics and 65 of these returned to the clinic for re-examination six weeks after confinement. A new health centre is to be built in the north of the town, and the isolation hospital is to be extended by the erection of a new 45-bed pavilion which will make possible the admission of cases of measles and whooping-cough now sent to Liverpool Public Assistance institutions.

West Bromwich.

The Hallam Hospital, which has been transferred from the guardians, is well situated in extensive grounds in a central but open part of the town. It is managed by the Health Committee, and has 474 beds and a visiting staff of eight physicians and surgeons. The senior visiting physician, Prof. Douglas Stanley, acts as medical superintendent, and Dr. W. Stott, the medical officer of health, as chief administrative officer. Prof. Stanley states that 4183 patients were admitted during the year; his report shows that the antenatal department has done excellent work; the hospital provides 26 maternity beds. Probationer nurses are sent to the fever wards in the isolation hospital for three months' duty. Dr. Stott points out that the accommodation at Hallam Hospital is 50 per cent. too great for the needs of West Bromwich and that it would be a serious matter if the outside authorities terminated their agreements with West Bromwich by which they share the use of this hospital. It would be a waste of the Hallam Hospital accommodation and of public money if other hospitals were built in the neighbourhood. An orthopædic centre is urgently needed, and it is hoped that this need will be met during the current year. A postnatal clinic under the visiting gynæcologist, Mr. J. S. M. Connell, is in existence at the Hallam Hospital at which it is proposed to give advice in selected cases on the question of birth control. Dr. Stott reports that breast-feeding is frequently discontinued without adequate reason, and it is estimated that only a little more than one-half of the babies are breast-fed. The records show that 46 babies were taken off the breast without medical advice before they were 14 days old, yet only five notices of "change to artificial feeding" were received from midwives.

Unfit houses in the borough are estimated to number 1300. During the last ten years 2278 municipal houses have been erected and there is a proposal to build a further 2000 during the next five years. It is difficult to find suitable sites within reasonable distance of the centre and of the works, owing to mining operations. In 1920, 35 areas, comprising 2871 houses, were represented as unhealthy, and since that date only one area has been cleared, although demolition is progressing in three others.

Eastbourne.

Dr. W. G. Willoughby reports that the altered arrangements under the Local Government Act were soon working smoothly. St. Mary's Hospital, transferred from the poor-law, is under the care of the Public Assistance Committee. One of the blocks, containing 22 beds, is used for infirm cases, and if these could be transferred to a simpler institution Dr. Willoughby considers the hospital accommodation in the borough would be adequate. At present there is a shortage of beds for children.

As regards the five years' housing programme, no area requires special consideration, but Dr. Willoughby thinks that 236 houses should be provided under the 1924 Act and 14 under the 1930 Act, and that 100 houses of the smaller type should be erected. He points out that there is a waste of municipal houses owing to change of the original needs of the tenants. It thus comes about that the committee goes on building while the older municipal houses are occupied by persons who have no special need of them.

More than a third of the births took place in the maternity home during 1930, and, including the extern cases, half the births in the borough were managed from the home. In all these cases antenatal work was carried out. Three local cases of undulant fever were reported in November and December, and a fourth had previously been removed to hospital from the rural district. The milk-supply was different for each patient and no goat infection or connexion between the four cases could be traced.

OBITUARY

EDWARD BEADON TURNER, F.R.C.S.

We announced last week the death of the well-known doctor and athlete, Mr. E. B. Turner, which occurred at his London residence on Tuesday, June 30th, in his 77th year. He had known during the last year the incurable nature of his infliction but bore the pain with uncomplaining courage, and his death may have come as a surprise to many friends.

MR. E. B. TURNER.

[Photograph by F. A. Swaine.

Born in 1854, Edward Beadon Turner was the elder son of the late Mr. George Turner, of Sherborne and Sussex Gardens, London. He went to Uppingham when, under Edward Thring's inspiration, the school was taking a high place among the English public schools. He has himself recorded in one of his many happy after dinner speeches, that he had a stormy career under that great teacher and disciplinarian, describing his progress to the upper sixth as having been "at the point of the cane"; but he left school with a sound classical training, besides winning many sporting trophies, and throughout his life made a hero of his old headmaster. In 1873 he proceeded for his medical education to St. George's Hospital, won a Brackenbury scholarship, took the English diplomas, and became house physician and assistant demonstrator of anatomy. In 1881 he obtained the F.R.C.S. and went into private practice in Sussex Gardens, where he resided until the end of his life and where he conducted a general practice with great ability, and also with extreme generosity towards his less affluent patients. The practice was always a good one, but, with Turner, ministry to the sick was ever in the front of his thoughts. In addition to private practice he was consulting physician to the Paddington Home of Rest and visiting apothecary at St. George's Hospital. But his record of public work was so full a one that his position as a doctor was somewhat obscured in the eyes of many who did not know that his forcible and clear-cut views on the promotion of the physical well-being of the nation and on the conduct and status of the medical profession were informed throughout by his personal experience as a successful practitioner.

It was not until the conflicts over national insurance arose that Turner manifested any overt interest in medical politics, but the early shape of the proposed legislation, with its unfortunate attitude towards medical practice, drew him into the conflict between the promoters of the Bill and the general practitioners of the country. He put his views and those of many others with conviction and fluency and was soon recognised as a courageous champion of medical rights. He devoted time and energy in demonstrating the injustices inherent in an immature piece of legislation, and when the struggle died down he remained convinced that the compromises, however largely they might have been in favour of the medical profession, were a mistake in result as well as in tactics. This work brought him into the prominent notice of the British Medical Association. He became a member of the council and for three years, 1915–18, was chairman of the Representative Body. In 1920 he was elected one of the Direct Representatives of the profession on the General Medical Council, a seat which he held for five years. At the Council meetings he exercised an influential voice, and on his retirement the President, in his annual delivery, said that Turner's presence would be missed as one "whose vigorous fluency of address and intimate acquaintance with divers sides of medical life and practice had often given colour to grey debates."

During the war Edward Turner did much valuable work. A chief medical officer of the special constabulary, he was selected for a special honour for bravery during an air raid, while he was untiring in his labours for promoting physical well-being among the soldiers. Day after day he gave counsel to our young army on the maintenance of health and on the avoidance of the risks of venereal disease to which they were subjected. His eloquent, sometimes homely, and always forcible deliveries were a source of strength and comfort to large numbers of lads during that long period of trial, and Turner's diary during those dark days would have constituted a claim for public recognition far higher than that which could be put forward for many who received high honours. In his public discourses on venereal disease he had the advantage of particular familiarity with the facts of its incidence, for from the first he had been prominent in the deliberations of the National Council for the Combating of Venereal Disease. And when the programme of that body became steadily enlarged, as the British Social Hygiene Council, with the necessary reconciliation of conflicting views among the leaders, Turner became chairman of the executive and propaganda committees, and a vice-president, being until the day of his death a moving spirit in its activities. He was a medallist of the Order of the British Empire, and a member of the Advisory Committee on Social Hygiene of the Colonial Office, and he wrote in various quarters in support of sanitary progress. But though he spoke regularly at meetings of medical societies he was an infrequent writer. In these columns and in the *British Medical Journal* he recorded his experiences of influenza epidemics in general practice, and he wrote in the Badminton library on cycling from the medical standpoint.

Turner was an enthusiastic sportsman. He came to St. George's Hospital as a winner of school athletic prizes and a keen footballer, and while at the hospital was a member of the Rugby football team which secured for three or four years in succession the inter-hospital cup for a small medical school. In 1875, while still a student, he was selected to play for England, and for the next three years he played for his country, once at least in an England team which included his younger brother, Sir George Turner. On the racing track he won many prizes, among others the inter-hospital mile, and was elected on the committee of the London Athletic Club of which he eventually became president. He was an enthusiastic devotee of the tricycle, and when his football days were over, and the exigencies of private practice filled his working day, he took up tricycling as a means of exercise, with the result that he broke the world's record, amateur and professional, for distances from 2 to 25 miles and eventually held all the records on the racing track, and (with S. Lee) the 50 mile tandem record on the road. Despite the fact that he had lost the sight of one eye, through diphtheritic infection incurred when he was a house physician, he became a first-class game shot, and at 40 years of age he took up yachting, owned, sailed, and raced a small yacht, and with characteristic enthusiasm worked for and obtained an extra-master's certificate in navigation, a possession which he shared with only two other amateurs.

Mr. Turner married Margaret Isobel, daughter of the late Henry Scott of Bombay and Hyde Park-street, London, who survives him and by whom he had four daughters.

WILLIAM ELDER, M.D., F.R.C.P., F.R.S.Edin.

Dr. William Elder, who died in Edinburgh on July 3rd, at the age of 66, came of a family of farmers well known in East Lothian. He graduated at the University of Edinburgh in 1885 and took the M.D. in 1896. After a resident post in the Infirmary and some experience of practice, he was appointed as assistant physician to Leith Hospital and a year later as full physician, retiring in 1909. He established a large general practice and soon became recognised as a thorough and reliable clinician; though technically a general practitioner, he developed the status of a consultant. From the beginning, he was especially interested in the central nervous system. His M.D. thesis, which gained a gold medal, was on Aphasia and the Cerebral Speech Mechanism, and later he published a book on "The Physical Basis of Memory" and contributed several articles to the *Encyclopædia Medica.* He wrote a number of papers on cerebral cases, on pernicious anæmia and other conditions emerging in his clinical work, but his primary interest was psychology, both normal and morbid. His last book, "Studies in Psychology," was a careful study of memory, emotion, consciousness, sleep, dreams, and allied mental phenomena. The book indicates wide reading, checked and criticised by clinical experience, and is full of interesting argument. His practical criticism of psychotherapeutic methods was the work of a reflective physician, who brought a wide general culture to the assistance of his profession.

Dr. Elder is survived by his wife, Dr. Eleanor Russell. A younger brother, George Elder, a man of equally great promise, died many years ago.

MEDICAL NEWS

Royal College of Surgeons of England.

On July 2nd three Fellows were elected into the Council to fill the vacancies caused by the retirement in rotation of Mr. J. Herbert Fisher, Mr. G. E. Gask, and Mr. Graham Simpson. The result of the poll was as follows:—

ELECTED—	Votes.	Plumpers.
Graham Scales Simpson	659	73
George Ernest Gask	635	12
Albert James Walton	544	35

In all 1105 Fellows voted, including 193 Fellows resident out of Great Britain and Ireland; in addition one vote was found to be invalid and six were received too late. Mr. Simpson and Mr. Gask are re-elected and Mr. Walton is elected for the full period of eight years.

University of Liverpool.

At recent examinations the following candidates were successful:—

M.D.

S. Alstead, R. E. Horsfall, E. D. Irvine, J. Libman, and C. L. G. Pratt.

M.B. AND CH.B. WITH HONOURS.

Class I.—T. L. Hughes.
Class II.—W. J. Chisnall and A. L. Potter.

FINAL EXAMINATION FOR M.B. AND CH.B.

Part III. (1923 Regulations).—M. L. Kaufman.

Part B. (1921 Regs.).—H. T. Cank, L. M. Crooks, W. S. Diggle, H. G. Evans, I. Harris, J. H. Hughes, O. V. Jones, W. W. Laughland, T. E. Lennon, H. F. Loewenthal, A. J. Martinez, P. B. Moroney, J. Sytner, J. V. Tollington, Winifred Walls, A. R. Williams, D. I. A. Williams, and A. Wynroe.

D.P.H.

Part I.—Enid M. Hughes, D. H. Williams, and Mary G. T. Williams.

Part II.—A. C. Briffa.

D.T.M.

J. A. K. FitzGerald.

D.T.H.

F. E. Camps, E. R. Gauld, K. T. Moir, M. Salah el Din, and G. Verghese.

University of Durham.

At recent examinations the following candidates were successful:—

THIRD EXAMINATION FOR M.B. AND B.S.

Pathology, Pharmacology, Public Health, &c.—H. W. Beetham, Chandar Bhan Bhugra, A. G. Bowerbank, D. G. French, Dorothy D. Nichol, S. M. Parker, John Short, and R. T. Wordingham.

University of Birmingham.

On July 4th the following degrees and diplomas were conferred:—

M.D.—*A. C. R. Walton, G. H. Knight, and H. J. Williams.

* With honours

Ch.M.—James Gore.

M.B., Ch.B.—† H. N. Gregg, †A. G. W. Whitfield, and F. H. C. Beards, J. A. R. P. Cant, W. S. Coltart, H. L. N. Davies, R. J. de Carteret, T. A. S. Kennerley, Nancy Laughton, H. J. Riley, Eric Rudkin, M. H. Sherwell, and R. B. F. Usher-Somers.

L.D.S.—J. L. T. Davies, and S. J. Foster.

† With second-class Honours.

Victoria University of Manchester.

At recent examinations the following candidates were successful:—

CH.M.

A. A. Davies.

FINAL EXAMINATION FOR M.B. AND CH.B.

* T. S. Heslop.

* First-class Honours.

† Nancy N. Carter, † J. C. Smith, † G. G. E. Smyth, Frank Cort, H. B. Craigie, P. M. Crowe, Frank Livesey, Edith A. Longson, J. P. Longworth, Simon Mills, Gerald Ramage, John Scully, Barnet Stone, Isaac Sutton, Kenneth Todd, and C. H. T. Wade.

† Second-class Honours.

FINAL EXAMINATION FOR L.D.S.

Marion Bentz, Henry Dellow, G. W. Hargreaves, J. W. Lord, and Maurice Sheldon.

Fellowship of Medicine and Post-Graduate Medical Association.

A course in general medicine and surgery will be held at the Miller General Hospital from July 20th to 31st, daily, from 10.30 A.M. to 5.30 P.M. Though not restricted to practitioners, this course is primarily intended for them. A course in urology will be given at the All Saints' Hospital, Vauxhall Bridge-road, from August 4th to 29th. From the 17th to the 29th a course in Diseases of Children will be given at the Queen's Hospital for Children, Hackney-road. Courses in September will include: Diseases of the Chest, at the Brompton Hospital; Psychological Medicine, at the Bethlem Royal Hospital; Diseases of Infants, at the Infants' Hospital; ophthalmology, at the Central London Ophthalmic Hospital; and general medicine and surgery, at the Westminster Hospital, followed by a similar course at the Metropolitan Hospital. All syllabuses may be obtained from the Fellowship at 1, Wimpole-street, London, W.1.

COLLEGE Dr. Robert Fielg Library

Mental Hospitals Association.

The thirteenth annual meeting of this association will be held at the Guildhall, London, on Wednesday next, July 15th, at 11 A.M.

St. Thomas's Hospital Dinner.

The old students' dinner will be held on Friday, Oct. 2nd, at the Mayfair Hotel, Berkeley-street, London, with Mr. J. Herbert Fisher in the chair. A portrait of Sir Cuthbert Wallace, painted by Mr. George Harcourt, R.A., will be presented by the chairman.

A Hospital Garden Party.

On Wednesday last week the Prince of Wales lent the grounds of Marlborough House for a children's garden party in aid of the restoration fund of the Children's Hospital, Great Ormond-street. The occasion took the form of a fair with a large variety of amusements, and some of the numbered programmes carried prizes which were distributed by Sir James Barrie.

Course on Surgical Tuberculosis.

Under the direction of Dr. Etienne Sorrel, a course of 12 lectures on surgical tuberculosis and other affections of the locomotor system will be given at the Hôpital Maritime at Berck-Plage, Pas-de-Calais, France, from August 3rd to 14th. Particulars are obtainable from Dr. Delahaye at the hospital.

Hygiene and Nursing in the Tropics.

The British Red Cross Society will hold a course of nine lectures and demonstrations on Tropical Hygiene and Nursing, beginning on Monday, Sept. 28th, at 5.30 P.M. This course is intended for people going to warm climates for the first time. Particulars may be obtained from the county secretary, 9, Chesham-street, London, S.W.1.

Medical Uses of Seaside Resorts.

Dr. Carl Häberlin, of the Marine Hospital at Wyk, on the island of Föhr, near Heligoland, is opening a discussion at the Section of Hydrology and Climatology of the British Medical Association on the Treatment of Delicate Children at the Seaside. The Section is holding a reception for him at the Saffrons Rooms, Eastbourne, on Wednesday, July 22nd, at 5.30 P.M., and invites the attendance of members of the medical profession who are interested in the organisation and development of marine health resorts.

Rockefeller Medical Fellowships.

The Medical Research Council announce that, on behalf of the Rockefeller Foundation, they have awarded travelling Fellowships for 1931–32 to: Ernest Thomas Conybeare, M.B., of Guy's Hospital; Gordon Moncrieff Dean, M.B., of the Department of Surgery, Aberdeen University; Morris Harris Finkelstein, M.B., of the Department of Bacteriology, Edinburgh University; Owen Stanley Gibbs, M.B., late Professor of Pharmacology in Dalhousie University, Canada; Emanuel Mannie Lourie, M.B., of the Liverpool School of Tropical Medicine; Allan William Spence, M.R.C.P., of St. Bartholomew's Hospital; Conrad Hal Waddington, M.A., of the Strangeways Research Laboratory, Cambridge; and Kenneth Harold Watkins, F.R.C.S., of the Royal Infirmary, Manchester.

The Fellowships awarded to Dr. Gibbs and Mr. Waddington are tenable in Europe, the others at centres in the United States. Dr. Conybeare and Mr. Waddington have been appointed on modified conditions while receiving emoluments from other sources.

Royal Society of Tropical Medicine and Hygiene.

The Chalmers medal, founded in memory of the late Dr. Albert Chalmers, has been awarded to Dr. N. Hamilton Fairley for distinguished original work in tropical medicine, particularly on the serology of helminthic infections.

Benefaction for Research on Puerperal Fever.

At a dinner held on July 6th, at the Savoy Hotel, in aid of Queen Charlotte's Maternity Hospital rebuilding fund, Sir Thomas Horder stated that the Rockefeller Foundation had entrusted the Medical Research Council with funds to the value of £21,000, spread over seven years, to be used for the further assistance of research work into puerperal fever and other causes of maternal mortality, in which the Council were coöperating with the hospital.

Brighton and Hove Provident Dental Hospital.

This institution, which has for so many years carried on its work in Queen's-road, Brighton, is about to be transferred to new premises in Buckingham-road. To adapt the large private house into a hospital, and equip it suitably, will entail a large expense, and at the annual meeting of the governors on June 4th it was intimated that the hospital would be making its first big public appeal. In 1930, no fewer than 5589 patients were treated at the hospital, which was 615 more than in 1929. The great increase is attributed to the working of the Sussex provident scheme.

Hospital Libraries.

The trustees of the British Red Cross Society and Order of St. John Hospital Library will be at home on Wednesday, July 15th, at 5.45 for 6 P.M., in the new nurses' home of the Middlesex Hospital, London, W. The speaker will be Dr. Barrie Lambert, chairman of the central public health committee of the London County Council.—At a summer school to be held by the Library Association at Birmingham there will be a session for hospital librarians on August 22nd, at 11.30 A.M. Speakers will include Dr. Nairn Dobbie. Also, at the Library Association's annual conference at Cheltenham a session will be devoted to hospital libraries (August 31st, 5.30 P.M.) and Sir Bruce Bruce-Porter will give an address.

Post-graduate Training for Ship Surgeons.

On the recommendation of a committee consisting of representatives of the shipping companies, the Ministry of Health, the London School of Hygiene and Tropical Medicine, the Seamen's Hospital Society, and the British Medical Association, a programme for post-graduate courses for ship surgeons has been formulated, and some of the lectures and demonstrations began at the Devonport pathological laboratory of the Seamen's Hospital Society at Greenwich on Monday last, July 6th. The principal objects are to enable ship surgeons to take "refresher" courses, and for candidates for such posts to receive special instruction in many subjects—e.g., ship's hygiene, Board of Trade requirements, and clinical work, in their special application to conditions on board ship. Instruction on tropical medicine and hygiene will be given at the London School of Tropical Medicine and the Hospital for Tropical Diseases. Ship surgeons will be able to obtain a diploma for special efficiency in subjects germane to their calling, and although it is not proposed that this should be an essential qualification for appointments, the shipping companies have lent their support to the arrangements. Particulars are obtainable from the Seamen's Hospital Society, Greenwich.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS.

STERILISATION OF DEFECTIVES.

A BILL legalising the voluntary sterilisation of mental defectives will shortly be introduced in the House of Commons by Major A. G. Church. The object of the Bill is to make the sterilisation of mental defectives a lawful act upon their own application or that of their parents or guardians, the expression "guardian" including "any person who undertakes or performs towards a defective the duty of a parent or guardian or has charge of him." The voluntary nature of the Bill is well guarded. First, if the subject be capable of expressing willingness consent must be obtained; secondly, in the case of the married defective the other partner must agree; thirdly, the consent of the Board of Control must be obtained, and the operation must be approved by judicial authority—e.g., a bench of magistrates. The operative interference is defined in the Bill as follows:—

(1) The expression "sterilising operation" shall mean vasectomy, salpingectomy, and any other surgical operation whereby the patient is rendered incapable of procreation or child-bearing without the capacity to exercise the sexual functions being otherwise impaired.

(2) Any medical treatment which attains the same result as a sterilising operation with the same limitation in its effect as regards the sexual functions shall be treated as a sterilising operation for all the purposes of this Act.

CREWS' ACCOMMODATION ON BRITISH SHIPS.

Mr. GRAHAM, President of the Board of Trade, in reply to Sir Basil Peto, said that since the regulations as to crews' accommodation were last revised in 1923, the standard of accommodation has been rising, especially in new ships, in many of which the accommodation provided is above the minimum laid down in the regulations. Complaints, however, have been received that the accommodation on British ships is unsatisfactory, and compares unfavourably with that on certain foreign, especially Scandinavian, ships. These complaints are always investigated individually, but to obtain a true picture of the conditions throughout the British Mercantile, the Board of Trade arranged for a comprehensive survey by their surveyors, who were instructed when visiting ships in the normal course of their duties to investigate and furnish particulars of the condition of the crew spaces on all ships, both British and foreign, visited by them during the period December, 1927, to March, 1928. In addition, the Shipping Federation appointed in May, 1929, a special committee to advise owners as to arrangements for the comfort and convenience of crews. This committee has made two reports relating to the accommodation of seamen other than lascars, one dealing with new cargo ships of 1500 tons gross and upwards, and the other with new cargo ships below that tonnage. A number of valuable recommendations are made, many of which go beyond the existing Board of Trade regulations. Model plans are appended to the reports showing arrangements for the crew, which would give a floor area and cubic capacity considerably in excess of the present statutory minimum, and indicating that, in the great majority of new ships, including even those of relatively small tonnage, it should be possible to provide a separate messroom for the crew. A special arrangement of the sleeping berths avoids double tiers of bunks, and useful suggestions are made in connexion with washing and sanitary facilities. Central heating by hot water is recommended for ordinary cargo ships, other than tankers; the importance of adequate ventilation and heating is recognised. The provision of an isolation hospital on all large foreign-going cargo vessels is also recommended. The committee lays special stress on the proper supervision and cleansing of the crews' quarters, and suggests the imposition of penalties for failure. These recommendations, as originally made, applied particularly to new ships of 1500 tons gross and over, but the shipping federation have agreed with the Board of Trade that they should be adopted wherever practicable irrespective of the size of the ship. The reports have been examined in the Department and also by the Joint Advisory Committee of the Board of Trade and the Ministry of Health on the health of the Mercantile Marine, and the opinion, both of the Board and of the joint committee, is that if the recommendations are followed, a material improvement in the standard of accommodation will result. The recommendations have also been considered by the Merchant Shipping Advisory Committee who have expressed the opinion that the recommendations should be of great value in securing improvements in the accommodation provided in new ships. The Board of Trade have given their general approval and will take action to give effect to the recommendations. They are circulating to their surveyors particulars of the recommendations, instructing them to ascertain, in the case of all new ships, the proposals as regards crew spaces as early as possible, so that, if necessary, they can approach the owners and builders and discuss with them the possibility of making appropriate improvements. The reports do not deal in any great detail with existing ships, as there must, of necessity, be great difficulty in securing improvements involving structural alterations. But in lavatory and washing accommodation the Board agrees that much can be done, as well as by the substitution of metal bunks for wooden berths, and the proper lighting, ventilation, painting, and cleaning of the crews' quarters. The surveyors are being instructed to secure improvements of this nature in cases where the age and condition of the ships and the particular trades in which they are engaged warrant the improvements.

MINING INDUSTRY WELFARE.

On July 7th, in reply to a question by Mr. LAWTHER, who asked the Secretary for Mines if he could state the names of the members of the committee to investigate the work of the Mining Industry Welfare Act, Mr. SHINWELL (Secretary to the Mines Department) said that the committee had now been constituted as follows:—Viscount Chelmsford (chairman), Lord Erskine, M.P.; Mr. G. Macdonald, M.P.; Mr. G. Mander, M.P.; Mr. A. K. McCosh (nominated by the Mining Association of Great Britain); and Mr. Alfred Smith (nominated by the Miners Federation of Great Britain). The terms of reference would be: to inquire how far the objects of Section 20 of the Mining Industry Act, 1920, have been met, what remains to be done, and whether the scope of the fund and the existing machinery for its administration as defined in that Section and as developed in practice are satisfactory for the future; and to report on all these matters with particular reference to the question of the amount and duration of the levy in the future.

Rural Housing.

In the House of Commons on Tuesday, July 7th, the Financial Resolution authorising the Minister of Health and the Scottish Department of Health to assist rural district councils in England and county councils in Scotland to provide houses in rural areas was agreed to in committee.

In the House of Lords on July 7th, the Merchant Shipping (Safety and Load Line Convention) Bill was read the third time and passed. The Bethlem Hospital (Amendment) Bill passed the report stage. The Marriage (Prohibited Degrees of Relationship) Bill was read a second time.

HOUSE OF COMMONS.

WEDNESDAY, JULY 1ST.

Motor Accidents and Danger Signs.

Mr. HURD asked the Minister of Transport if his attention had been called to the increase of motor accidents, often fatal, through collisions at cross-roads; and whether he would approve of a standard form of danger sign to be erected at these points.—Mr. MORRISON replied: I am not aware of any evidence that motor accidents at cross-roads are increasing. There is already a standard international sign giving warning of the approach to cross-roads which has been erected in large numbers throughout the country. I propose shortly to review the whole question of road traffic signs in connexion with the provisions of Section 48 of the Road Traffic Act, 1930.

Foreign Strawberry Pulp and Preservatives.

Sir THOMAS INSKIP asked the Minister of Health (1) whether the use of chemicals such as sulphur dioxide or lime as preservatives would be allowed in the case of foreign strawberry pulp about to be imported during the next four weeks; and what steps he proposed to take to prevent the risk of injury to health by the use of such preservatives; and (2) whether he was aware that the importation of foreign strawberry pulp, dressed with sulphur dioxide or other chemicals as preservatives, was about to take place; and whether he was prepared to take such steps as might be open to him to prevent such importation and, if so, what steps.—Miss LAWRENCE replied: Under the Preservatives Regulations the only chemical preservatives allowed in strawberry pulp are sulphur dioxide and sulphites. My right hon. friend understands that the use of these preservatives is regarded as a commercial necessity for both home-produced and foreign fruit, and in view of the small residual amount allowed in the jam made from the pulp he does not think that he would be justified in amending the regulations so as to prohibit their use.

THURSDAY, JULY 2ND.

Pharmacy and Poisons Bill.

Mr. BROMLEY asked the Home Secretary whether he had considered the representations made to him by the pharmaceutical organisations on the subject of the Pharmacy and Poisons Bill; and whether he proposed to take any steps to meet the objections raised by these organisations.—Mr. CLYNES replied: As there has been a good deal of misunderstanding about the scope and objects of the Poisons and Pharmacy Bill, I crave indulgence for a somewhat lengthy statement. This Bill is based upon the recommendations of a Departmental Committee which was appointed by the previous Administration, and reported in 1930. The committee which, apart from its pharmaceutical members, was entirely independent of any of the commercial interests affected, found that the existing position relating to poisons was far from satisfactory, and the object of the present Bill is to provide for a wider and much more effective regulation of poisons than exists at present. I understand that the pharmaceutical associations take exception to the Bill on two main grounds. In the first place they demand that all doctors' prescriptions, whether they contain poisons or not, shall be dispensed by registered pharmacists only. This proposal does not, however, come within the scope of the Bill. Moreover, it has never been investigated, and even if it were assumed that there was a prima facie case for considering that the demand is in the public interest, the Government could not ask Parliament to adopt such a proposal except after adequate inquiry and after the interests of those who would be affected by the prohibition had had opportunity of stating their case. Secondly, the pharmacists demand that the increased facilities which the Bill proposes for the supply to farmers of agricultural poisons shall be limited to firms carrying on a bona fide business in the supply of agricultural requisites. I am advised by the Minister of Agriculture and by the Board of Agriculture for Scotland that this limitation would not make adequate provision for legitimate needs in the more rural districts. The Government, however, have decided to propose an amendment to the Bill which will have the effect of requiring the Poisons Board and the Secretary of State, in considering the allocation of poisons as between Part I. and Part II., to have regard to the desirability of restricting the contents of Part II. (which will contain the list of poisons which may be sold by persons other than pharmaceutical chemists) so far as is consistent with the provision of adequate facilities for the public to obtain supplies of non-medical substances which are in common use.

Schools for Mentally Defective Children.

Mrs. MANNING asked the President of the Board of Education the number of special schools for mentally defective children which had been opened during the years 1926, 1927, 1928, 1929 and 1930 respectively.—Mr. LEES-SMITH replied: The numbers of special schools for mentally defective children open during the years in question were five in 1926, four in 1927, none in 1928, four in 1929, and one in 1930.

Insured Persons and Sickness Benefit.

The Marquess of TITCHFIELD asked the Minister of Health whether he had read the report by Sir Walter Kinnear, the Controller of the National Health Insurance Department, which stated that a recent investigation showed that 12 persons out of 100 were drawing sickness benefit when they were capable of returning to work; and whether he proposed to take any steps to rectify this state of affairs.—Mr. GREENWOOD replied: I am aware of the statement referred to, which was to the effect that out of a large and representative group of insured persons who were in receipt of sickness or disablement benefit on a certain day, and whose title to benefit was made the subject of special investigation, it was found that 12 per cent. were capable of work and consequently not entitled to benefit. I have already addressed circulars to all approved societies and to all insurance medical practitioners on the steps to be taken to avoid payment of benefit to persons not entitled thereto, and I would also refer the noble Lord to the reply which I gave to the right hon. Member for West Woolwich on June 18th.

Slum Clearance and Plague of Vermin.

Sir MARTIN CONWAY asked the Minister of Health whether he was aware that, owing to the recent destruction of some slum houses in Westminster which belonged to the London County Council, a plague of vermin, notably of the species *Acanthia lectularia*, had invaded certain streets within the borough; and whether he would take steps to see that the municipal authorities disinfected the houses attacked by this pest, seeing that the insects in question were well-known carriers of infection of certain diseases.—Mr. GREENWOOD replied: I was not previously aware of the facts stated in the first part of the question. I have no power to give directions to the local authorities in this matter, but I will communicate with them and inform the hon. Member of the result.

Sir M. CONWAY: Is the right hon. gentleman aware that the female of this enterprising insect lays eggs four times a year, 50 at a time, so that the eradication of a pest of that sort exceeds the powers of the dwellers in most private houses; and will he call the attention of the Westminster municipal authorities to the fact that the Chelsea municipal authorities undertake the extirpation of this enterprising insect, and ask them if they will follow the example of Chelsea?

Mr. GREENWOOD: I will certainly do my best to bring this interesting information to their notice.

Protection Against Poison Gas.

Brigadier-General CLIFTON BROWN asked the Prime Minister whether, in view of the scheme detailing measures which should be taken for the protection of civilians from poison gas which was recommended by an international committee of experts in 1928, any steps had been taken on the matter in this country; and what steps had been taken by foreign nations.—Mr. MACDONALD replied: The report to which the hon. and gallant Member refers has been brought before the Standing Subcommittee of the Committee of Imperial Defence concerned with these matters. Various foreign nations are known to be actively studying this question, but I am unable to say what steps they are taking. As I have said in answer to previous questions on this subject, the ratification of the Geneva Gas Protocol of 1925 by most of the countries in Europe provides an important safeguard against this form of attack.

Registration of Illegitimate Children.

Mr. DAY asked the Minister of Health whether, in view of the present regulations existing for the registration of illegitimate children, he would consider the introduction of legislation which would have as its object the registration of the birth of these children in such a way that they did not bear the stigma of illegitimacy.—Mr. GREENWOOD replied: I would remind the hon. Member that the primary object of birth registration is the establishment of a record for the purpose of furnishing legal evidence in regard to matters of civil status, and that so long as a distinction is drawn by the law for many important purposes between legitimate and illegitimate children, the obliteration of this distinction in the birth register would merely destroy its utility to a very large extent, without affording any compensating advantages to the individuals affected.

MONDAY, JULY 6TH.

Nursery Schools.

Dr. HASTINGS asked the President of the Board of Education the number of nursery schools completed, being built and sanctioned in connexion with provided and unprovided schools to date, and how many of these schools in each class were of the open-air type.—Mr. MORGAN-JONES (Parliamentary Secretary to the Board of Education) replied: There are 44 nursery schools recognised by the Board of Education, 23 being provided schools, and 21 voluntary schools. There are 11 provided, and three voluntary schools in course of erection. In addition, preliminary proposals have been sanctioned for 12 provided schools. Practically all the schools now being built are open-air schools; of the existing schools the majority are planned on open-air lines, and the remainder have good open-air facilities.

Post-graduate Medical School.

Dr. HASTINGS asked the Minister of Health what progress was being made in the arrangements for post-graduate teaching in the Hammersmith Hospital.—Miss SUSAN LAWRENCE (Parliamentary Secretary to the Ministry of Health) replied: A Royal Charter constituting the Governing Body of the British Post-graduate Medical School and defining the functions of the Governors was approved by the King in Council on June 29th; and active steps are being taken, in collaboration with the London County Council to proceed as quickly as possible with the planning and building of the school, and with the adaptation of the hospital for the purposes of post-graduate medical education.

Dr. HASTINGS asked if Miss Lawrence had any idea when the school would be opened for teaching purposes.

Miss LAWRENCE said that she could not say at the present moment.

A RAILWAY BED.—A bed in the Norfolk and Norwich Hospital has recently been endowed by the London and North-Eastern Railway staff hospital fund of the Norwich district. It has been named "The Drury Bed," in recognition of the services to the institution of Mr. H. W. C. Drury, who until recently was superintendent of the Norwich district of the railway.

Appointments

HOLDERNESS, R. C., M.B., B.S. Lond., D.P.H., has been appointed Asst. Medical Officer of Health, Bury.

City of London Maternity Hospital, City-road, E.C.: WALLACE W. H. S., M.B., B.S.Lond., Resident Medical Officer, and BARBER, A., L.R.C.P. Lond., M.R.C.S., Assist. Resident Medical Officer.

Certifying Surgeons under the Factory and Workshop Acts: HILL, R. M., M.B., Ch.B. Glasg. (Tooting); CRAIG, J. (Grosmont, York).

Vacancies

☞ *For further information refer to the advertisement columns.*

Aberdeen, City of.—M.O. in charge of the Council's Mental Health Services. £950.

Accrington, Victoria Hospital.—H.S. £150.

All Saints' Hospital for Genito-Urinary Diseases, 91, Finchley-road, N.W.—H.S. At rate of £150.

Barnsley, Beckett Hospital and Dispensary.—Cas. O. and H.P. £250 and £200 respectively.

Beckenham, Kent, Bethlem Hospital, Monks Orchard, Eden Park. Res. H.P. At rate of £150.

Birmingham Ear and Throat Hospital, Edmond-street.—H.S. At rate of £200.

Birmingham General Hospital.—Two Res. Anæsthetists. Each £120. Also Res. H.P. and three Res. H.S.'s. Each £70.

Birmingham, Midland Hospital, Easy-row.—H.S. £150.

Birmingham P.H. Dept., Tuberculosis Section.—Asst. M.O. £400.

Birmingham, Queen's Hospital.—H.S. for Ear, Nose, and Throat. Also H.P. for Birmingham and Midland Nerve Hospital. Each at rate of £70. Also Dental H.S. At rate of £50–£70.

Birmingham, Selly Oak Hospital.—Casualty O. At rate of £200.

Blackburn County Borough.—Asst. M.O.H. and Asst. School M.O. £500.

Bolton Infirmary and Dispensary.—Two H.S.'s. Each £150.

Bradford Children's Hospital.—H.P. £120.

Bradford Royal Infirmary.—Three H.S.'s. Each £150.

Brighton, New Sussex Hospital, for Women and Children.—Hon. Asst. Ophth. S. Also H.P. and H.S. Each £100.

Brighton, Royal Sussex County Hospital.—Two Hon. Med. Registrars. Also three Hon. Surg. Registrars.

Bristol Eye Hospital.—Asst. Res. H.S. £100.

Bristol Royal Infirmary.—Sen. Res. M.O. £200. Also Res. Dental H.S. and Res. Cas. H.S. Each £80. Also Res. H.P.'s and H.S.'s. All at rate of £60. Also Hon. Asst. to Obstetric Dept.

Bury Infirmary, Lancs.—Third H.S. At rate of £150.

Chester, East Lancashire Tuberculosis Colony, Barrowmore Hall, Great Barrow.—Asst. M.O. At rate of £275.

Dreadnought Hospital, Greenwich.—Physician, for Dept. of Physical Medicine. 50 guineas.

Dudley, Guest Hospital.—Two H.S.'s Each £160–£170.

Durham County Hospital.—Two H.S.'s. Each £150.

Durham University College of Medicine.—Jun. Demonstrator in Physiology. £250–£300.

East London Hospital for Children, &c., Shadwell, E.—H.S. and Cas. O. £125.

Evelina Hospital for Children, Southwark, S.E.—H.S. At rate of £120.

Exeter, Royal Devon and Exeter Hospital.—H.P. Also H.S. to Spec. Depts. Each at rate of £150.

Folkestone, Royal Victoria Hospital.—Sen. and Jun. Res. M.O.'s. At rate of £125 and £100 respectively.

Great Yarmouth General Hospital.—H.S. £140.

Hampstead General and North-West London Hospital, Haverstock-hill, N.W.—Cas. Surg. O. for Out-patient Dept. At rate of £100. Also H.P. At rate of £100.

Hove, Lady Chichester Hospital.—Jun. H.P. At rate of £50.

Huddersfield Royal Infirmary.—H.S. At rate of £150.

Hull Royal Infirmary.—3rd H.S. At rate of £150.

Inverness, Royal Northern Infirmary.—Two H.S.'s. Each at rate of £100.

Ipswich, East Suffolk and Ipswich Hospital.—Cas. O. £120.

King Edward Memorial Hospital, Ealing, W.—Sen. and Jun. Res. M.O.'s. £250 and £150 respectively.

King's Lynn, West Norfolk and King's Lynn General Hospital.—H.P. At rate of £150.

Kingston-upon-Hull, City and County of.—M.O.H. £1500. Also Sen. Asst. M.O.H. for Maternity and Child Welfare Dept. £800.

Lancaster Royal Infirmary.—Jun. H.S. £130.

Leamington Spa, Warneford, General Hospital.—Hon. Surgeon for Diseases of Ear, Nose, and Throat.

Leeds Hospital for Women.—H.S. £100.

Leeds, Tuberculosis Sanatorium, Killingbeck.—Sen. Asst. Res. M.O. £350.

Leicester Royal Infirmary.—Sen. M.O. for Veneral Diseases Dept. £500.

Liverpool Royal, Babies' Hospital, Woolton, and Crofton Recovery Hospital for Women, Aigburth.—M.O. At rate of £200.

Liverpool Royal, Children's Hospital.—Res. M.O. and second Res. M.O. for Heswall Branch. At rate of £180 and £120 respectively. Also two Res. H.P.'s and two Res. H.S.'s for City Branch, Myrtle-street. All at rate of £100.

London Hospital, E.—Hon. Asst. Anæsthetist.

London Light and Electrical Clinic, Ranelagh-road, S.W.—Med. Reg. £300.

Manchester, City Education Committee.—Asst. School M.O. £600.

Manchester Royal Eye Hospital.—Jun. H.S. £120.

Manchester, St. Mary's Hospitals.—Five H.S.'s. All at rate of £50.

Manchester Victoria Memorial Jewish Hospital, Cheetham.—Jun. H.S. At rate of £125.

Manor House Hospital, Golders Green, N.W.—Jun. M.O. £200

Maudsley Hospital, Denmark Hill, S.E.—Asst. M.O. £475.

Middlesex County Council.—Ophthalmic Surgeon. £2 12*s.* 6*d.* per session.

Nottingham General Hospital.—Cas. O. At rate of £200.

Plymouth, South Devon and East Cornwall Hospital.—H.S. At rate of £100.

Queen Mary's Hospital for the East End, E.—H.P.

Queen's Hospital for Children, Hackney-road, E.—Res. M.O. At rate of £200.

Reading, Royal Berkshire Hospital.—Res. Anæsthetist. At rate of £150.

Rotherham Hospital.—Cas. H.S. £150. Also H.P. £180.

Royal Northern Hospital, Holloway, N.—Asst. Pathologist. £500.

St. John's Hospital, Lewisham, S.E.—H.S. and Cas. O. Each at rate of £100.

St. Leonard's-on-Sea, Buchanan Hospital.—Jun. H.S. £125.

St. Mark's Hospital for Cancer, Fistula, &c., City-road, E.C.—H.S. At rate of £75.

St. Thomas's Hospital Medical School, S.E.—Sen. Demonstrator in Anatomy. £500.

Scunthorpe and District War Memorial Hospital.—Res. Surgeon. Also second H.S. £250 and £150 respectively.

Sheffield Children's Hospital.—3rd Res. M.O. At rate of £80.

Sheffield, Jessop Hospital for Women.—Asst. H.S. At rate of £100.

Sheffield Royal Hospital.—Cas. O. and Ophth. H.S. £150 and £120 respectively. Also Res. Anæsthetist. At rate of £80.

Sheffield Royal Infirmary.—H.S., Ophth. H.S., Asst. Aural and Ophth. H.S. Each at rate of £80.

Society of Apothecaries of London, Water-lane, Queen Victoria-street, E.C.—Examinership.

Southampton, Free Eye Hospital.—H.S.

South London Hospital for Women, South Side, Clapham Common, S.W.—Two H.S.'s. Each at rate of £100.

South Shields, Ingham Infirmary.—H.S. £150.

Stafford, County Bacteriological Laboratory.—Bacteriologist. 12 guineas per week.

Stockport Infirmary.—H.S. £175.

Sutton, Sutton and Cheam Hospital.—Res. M.O. At rate of £100.

Swansea General and Eye Hospital.—H.P. £150. Also Asst. Pathologist. £500.

Talgarth, Breconshire, South Wales Sanatorium.—Jun. Asst. Res. M.O. £250.

Victoria Hospital for Children, Tite-street, Chelsea, S.W.—H.P. and H.S. Each at rate of £100.

Warrington Infirmary and Dispensary.—Jun. H.S. £175.

Warwick County Mental Hospital, Hatton.—Second Asst. M.O. £450.

Willesden General Hospital, N.W.—H.P. and H.S. At rate of £100 and £110 respectively. Also Registrars.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Moreton-in-Marsh (Gloucestershire); at Carmarthen (Carmarthenshire); at Bedford (Beds.); at Lutterworth (Leicestershire); and at Holywell (Flints).

Births, Marriages, and Deaths

BIRTHS.

HUNT.—On July 1st, at Welbeck-street, W., the wife of Dr. W. S. Hunt, of a son.

SADLIER.—On July 1st, at "Brown Heath," Buxted, Sussex, the wife of Dr. H. W. Sadlier, of a son.

MARRIAGES.

FAINGES—SMYTH.—On July 4th, 1931, at St. Peter's, Battersea, by the Rev. G. Bell, assisted by Rev. J. M. Cobbett, Donald Sutherland, youngest son of James Fainges, Esq., of Brisbane, Australia, to Doreen Croly, only daughter of Dr. James and Mrs. Smyth, of 382, Upper Richmond-road, Putney, S.W.

GILLESPIE—WALLACE.—On June 30th, at St. George's West Church, Edinburgh, Alexander MacAndrew Gillespie, M.B., D.T.M., M.R.C.P. (Edin.), F.R.G.S., West African Medical Staff, to Mary Agnes, youngest daughter of the late William Wallace and of Mrs. Wallace, Cairnie-street, Arbroath, Angus.

MOYNIHAN—FERGUSON.—On July 4th, at St. Mark's Surbiton, John Holmes Moynihan, M.R.C.S., L.R.C.P., to Sheila Janet Ferguson, M.R.C.S., L.R.C.P., only daughter of Mr. and Mrs. Ferguson, Ardmay Surbiton.

SAVIN—GRIFFITH.—On Saturday, July 4th, 1931, at Wimbledon, Lewis Herbert Savin, M.D., M.R.C.P., F.R.C.S., son of the late Lewis Savin, M.R.C.S., to Mary Helen Griffith, elder daughter of the late Mr. and Mrs. Walter Griffith.

SHAW—GRICE.—On June 30th, at St. Peter's, Caversham, Wilfred Shaw, M.D., F.R.C.S., to Frances Anne, third daughter of Mr. and Mrs. A. G. Grice, of Caversham.

DEATHS.

ANDERSON.—On July 2nd, 1931, at a Manchester Nursing Home, George Reinhardt Anderson, J.P., M.B.E., F.R.C.S., of 45, Westbourne-road, Southport, the beloved husband of Annie Eleanor Anderson. Service at Mornington-road Wesleyan Church, Southport, on Monday last. Funeral at Birkdale Cemetery.

JONES.—On June 29th, at Elm Tree House, High Halden, Kent, Dr. Isaac Stephenson Jones, aged 82.

TURNER.—On June 30th, at Westbourne-terrace, W., Edward Beadon Turner, F.R.C.S., aged 76.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

THE WORK OF AN INDUSTRIAL CLINIC.

By N. Howard Mummery, M.R.C.S. Eng.[1]

[Colonel Mummery began his lecture with a pertinent résumé of the progress made in this country during the nineteenth and especially the twentieth century in the promotion of industrial health, as instanced by the abolition of child labour and the developments in welfare organisation which have marked the world since the close of the war. He continued :—]

The British Position.

"In this country much has been done, but it appears that out of 142,000 factories and 133,000 workshops, large and small, only 2200 of the larger concerns—88 per cent. of which are factories—have so far adopted welfare schemes and employ nurses. Details obtained from 1006 of these concerns show that between them they employ 2022 nurses, of whom 1833 are female and 180 male; 91 per cent. of the female nurses are registered, but only 25 per cent. of the male. The average number of employees per nurse is 963. Of the 1006 industrial concerns providing details, 91 per cent. employ doctors on a full or part-time basis. It is known, however, that the number of medical men and women devoting themselves to this most important branch of professional work is steadily increasing in spite of industrial depression, and the available applicants for such posts greatly exceed the demand."

Commenting on this increase of popularity, Colonel Mummery called attention to Sir George Newman's estimate "that about 50 per cent. of the insured population of England and Wales go on the sick-list every year, and, as the average annual absence from work is computed by him to be 3·73 weeks, we are faced with the appalling fact that seven million persons lose between them 25 million working weeks annually. And although the standard of life has risen and mortality has fallen, sickness claims have risen since the recent war by 41 per cent. for men, 60 per cent. for unmarried women, and 106 per cent. for married women, while, says Sir Thomas Oliver (*Journal of State Medicine,* August, 1930), within the last 30 years the length of sickness has increased from 16½ days to 28 days."

Various factors responsible for the alleged increase in disability, or morbidity, rates, and probably all are contributing to it, were mentioned by the lecturer, who also referred to the difficulties of the panel practitioner in the matter of signing medical certificates to the satisfaction of patients, societies, and medical referees. He continued :—

State Assistance.

"To a large extent the old incentive of 'work or starve' has given way in many cases to an over-liberal State assistance; and we see the public in increasing numbers overwhelming the voluntary hospitals where the staffs are inadequate to supervise economically the period that elapses between restoration of function after injury—or recovery from illness—and the subsequent return to useful paid employment. To these factors tending to increase morbidity statistics one must, strangely enough, add welfare work itself, for recent reports of the Division of Research, Office of Industrial Hygiene, and the United States Public Health Service, show, in that country, that the welfare provision of granting wages during sick absence from work definitely prolongs such absence. Two large industrial concerns in the same metropolitan area and under similar general conditions were compared, and it was found that if wages were entirely lost while the worker was absent on account of illness, the record of absence was much lower for illnesses of short duration than when full wages were paid during such absence. This was attributed, not to malingering, but to the fact that employees tended to stay at home and take more care of their ailments, such as colds, which they could not afford to do if wages were lost at such times. But the conclusion was reached that however advantageous it might appear to employers to pay only for time worked, or for sick benefit societies to withhold sick benefit during the first week's disability, the fact remains that the spreading of disease, which entails such heavy industrial losses, is facilitated by the worker continuing at work, or returning to it, while ill. Lack of provision for sick leave and sick pay falls heavily not only on the employee, but indirectly upon the employer too, and militates against improvement in the public health. The reports referred to—which may be studied with benefit in the *Journal of Industrial Hygiene* for November and December, 1930—confirm others published in this country that the incidence of industrial sick absence is most prevalent among the younger workers and affects the females more than the males; that the duration of sick absence increases with the age of the workers, largely owing to the more serious diseases tending to occur at the later ages when recuperative ability is waning—though it is interesting to note that a group of employees over 70 years of age compared very favourably, as regards annual disability absence, with the younger age-groups.

"In this country we recognise that the State has made provision for the industrial population during physical incapacity by means of National Health Insurance and Workmen's Compensation and Employers' Liability Acts. Some short-sighted employers seem to think that by paying their statutory contributions under the first-named Act, and insuring themselves against the risks of the latter Acts, they are doing all that can reasonably be expected of them and all that good business management calls for. They are unable to see the importance of the personal factor in industry which demands careful study if the best service is to be obtained, and forget that skilled workers cannot be trained in a day, and that nothing is more wasteful than excessive labour turnover and an unduly large absentee list. These State enactments, good as they are, fail to meet fully the needs of the industrial population or those of industry itself. They need supplementary and alternative services which the employer alone is able economically to provide. Industrial welfare provides such additional services as an integral part of good management. It is purely a voluntary service initiated, financed, and controlled by the employer, and not, as a rule, contributed to by the workpeople, nor assisted by the State—though with official recognition of its value certain Home Office regulations and inspections have followed, requiring certain minimum standards in various trades. Welfare services are not, and never should be, mere philanthropic side-shows. They are part of competent industrial management, and a factor in production. They should stand the acid test of their value to the community as a whole, and of their value in assisting the conduct of the industrial or commercial concern to earn good profits and pay good wages. If a welfare scheme fails in either of these directions it becomes a costly form of philanthropy, but it will not fail if conceived and conducted on right lines, and the employer who cares adequately for the well-being and well-doing of the workpeople upon whom his success depends is an astute business man as well as a good citizen. Like all social schemes that are designed to assist the less fortunate members of the community there is always the danger that welfare work may tend to lessen individual self-reliance and foster a dependency upon others that is bad both for the individual himself and for the State. Therefore, assistance should supplement, but not replace, the individual efforts of the employee to make adequate provision for himself and his dependents. In all insurance schemes it is essential to their success that they should be drawn upon as little as possible, only in emergencies, and not at regular intervals as a reward for abstention in the interim. In America the view is held that 'wealth is not *in* industry, but that wealth *is* industry, and that every single thing given for nothing or in return for inadequate service is, in effect, so much actual poverty grafted on to the nation. Thus, abuse of any system of insurance is wilful robbery of other people's livelihood and high treason against the State.'

---

[1] A lecture to the Public Health Division, London School of Hygiene and Tropical Medicine, on May 29th, 1931, by N. Howard Mummery, M.R.C.S. Eng., Lieut.-Col., late R.A.M.C. (Temp.); medical officer in charge, Cadby Hall Clinic, J. Lyons and Co., Ltd.

Industrial Health Research Board.

"The Industrial Health Research Board owes its origin to the Health of Munition Workers Committee set up during the war. That Committee, in 1916, recommended that proper organisation of medical services in factories was essential not only for the health of the operatives, but in order to secure improved production and output by preventing loss of time and efficiency among the workers. The Board has the responsibility of investigating such problems as the relationship of age to capacity for work; the influence of diet, alcohol, nutrition, and other factors upon human efficiency; the maximum loads, height of work-benches and chairs most desirable, and, generally speaking, the application of physiology to industrial processes. It places the resources of physiological, psychological, and medical science at the disposal of industrial management. With the individual firm's welfare department and medical officer, however, rests the actual detailed work which a solution of all these problems demands, and in actual practice it is found that many theories, apparently excellent in principle, have to be modified in their application to industrial processes before they are acceptable to the management. Any drastic alteration usually involves initial expense and arouses prompt opposition, frequently from those whom it is most designed to assist. Therefore, physiologists and medical men need to appreciate more fully their need of a wider knowledge of industrial management and industrial processes if their knowledge is to be of the fullest possible assistance to industry.

Industrial Welfare Clinic.

"It will readily be understood that the comprehensive task of caring for factory personnel necessitates the welfare department of a firm interesting itself in almost every factory activity. It is concerned with the engagement and discharge of workers; with their medical examination to determine fitness for the particular job; with the prevention and cure of injuries and illness; with the lighting, heating, ventilation, and cleaning of workrooms; with the working clothing of factory operatives whose almost ineradicable preference for the shoddiest of footwear is so largely responsible for colds and rheumatism; with feeding, housing, and recreation; and, in a large concern, with continuation schools, handwork guilds, and even in creating a social life for its employees by means of clubs and sports-grounds. Its activities extend beyond the factory precincts into the homes of the workpeople, where the welfare visitor keeps in touch with them during illness, and into the hospitals and other institutions into which they may go.

"Welfare work necessarily must vary widely with, and be governed by, the size and resources of the individual firm; by the urban or rural distribution of its employees, and by the policy of its directors. It varies indeed from the statutory first-aid box per 150 employees, at the bottom of the scale, to the provision of an up-to-date hospital clinic, comprising doctors, nurses, dentists, masseurs, at the top of the scale. Many of these welfare activities are in the hands of the lay superintendent and assistants of the department, and I am confining myself to those which more directly come within the scope of the clinic attached to it. The lay-out or plan of such a clinic is important. It should be easy of access from all parts of the factory, and as far as possible away from noise. The essential features are: A waiting-room with seating accommodation under clerical supervision, with an ample filing-room near the entrance. Each employee on arrival and departure is given a time check showing the time spent at the clinic; this he takes back to his manager with any necessary report from the medical officer. Details of every attendance at the clinic are carefully recorded on clinical cards, which, together with the medical officer's notes of condition on engagement, previous illness or injuries, and all other relative documents, are kept in cardboard folders in the filing-room. The surgery, fitted with basins, foot-bath, hot and cold running water, and necessary tables, chairs, cupboards, &c., should communicate through a curtain with the doctor's consulting-room, and on each side of the inter-communicating doorway should be a small dressing-room containing a couch and chairs. These are invaluable when patients have to be got ready for examination. A separate rest room for serious cases is also a necessity. The equipment of the doctor's room should include facilities for vision testing and most of the ordinary aids to clinical diagnosis, among which an X ray apparatus will be found particularly valuable."

FUNCTIONS OF AN INDUSTRIAL CLINIC.

These, said the lecturer, include all means, preventive and remedial, taken to reduce to a minimum the working time lost by employees owing to illness and accidents.

The Medical Examination.

"First in importance is the medical examination of all candidates for employment, carried out with special regard to the nature of the work—not in order to select only the fittest and reject all those who have disabilities, but rather to place all candidates with satisfactory references in work at which the defect or weakness will not be aggravated, unduly increase the industrial risk borne by the employer, nor prove a bar to efficient and profitable employment. Few people are completely healthy, and Dr. René Sand has stated (THE LANCET, August 23rd, 1930) that though 80 per cent. have healthy hearts, lungs, and kidneys, normal weight and posture are enjoyed by less than 50 per cent. of people who think themselves fit; less than half have normal vision, normal teeth, or a normal nasopharynx; and about 40 per cent. have habitual constipation. Actually the number of applicants rejected is surprisingly low. In 1929 I examined 2675 men and women for employment, and rejected only 3 per cent., and in 1930 2415 with 2·4 per cent. of rejections. The factory doctor undertaking this vocational selection must be familiar with the various processes of manufacture and distribution in his factory, and will have tabulated these processes, recording against each group of workers the disabilities which should prohibit such employment, and what special attributes each process calls for. He will have tried to discover any special capacity or characteristic, or even physical disability, that is common to the best workers in any group and lacking in the others, and will endeavour to pick out for employment those who seem to possess it. A few illustrations will serve. Telephone operators should be of average height to work comfortably at the exchange switchboard; they should have well-developed back muscles, good hearing, and memory for spoken numbers, good sight, and a clear enunciation, be capable of sustained attention with a short time reaction, and an equable temperament, and be free of naso-aural-pharyngeal disease. Motor drivers are required to have a minimum vision of six-twelfths normal in each eye, and to be free of corneal opacities likely to occlude the contracted iris in a bright light at night. Epilepsy, petit mal, cardiovascular disease, or marked deafness is a disqualification. Bakers, pastry-cooks, confectioners, and others exposed to recognised trade irritants, call for special attention to the skin state, any marked degree of seborrhœa, ichthyosis, hyperidrosis, or endocrine-sympathetic unbalance, causing chilblains and purple extremities, being disqualifications. Cleaners and scrubbers are exposed to soda irritation and water maceration of the hands, and to tibial bursitis from kneeling. Special attention, therefore, is directed to the state of these parts. Porters are specially examined for hernia and as to general development. Waitresses require examination for signs of weak spinal muscles tending to scoliosis, which is apt to develop from carrying heavy trays on the left arm, and for any tendency to pes planus, which is common among them. Naturally, the doctor is supplied, on a convenient form, with particulars of the employment suggested. Working on a definite routine with the aid of trained nurses, who, in the case of women and girls, make a complete preliminary inspection, these examinations can be carried out rapidly and with a surprisingly high degree of accuracy in spite of the fact that where large numbers have to be seen the scope of the examination cannot always include urinary and certain other desirable tests unless there is reason to suspect their special desirability. No opposition to these examinations has been experienced, either from the individuals themselves or from trade-unions, and it is difficult to understand how there could be any when the object of the examination is so clearly in the interests of both.

Periodic Re-examination.—Examination on Return.

"The periodic re-examination of young or underdeveloped persons and of those exposed to special occupational risk is essential. This includes the weekly inspection of the skin of all workers handling sugar, flour, dough, cream icing, and other known irritants. As will be mentioned later, the weekly manicure of such employees also provides a valuable means of watching for early signs of dermatoses and referring them to the medical officer. The record of weight taken on engagement provides a valuable means of checking the physical development of young persons, a very large number of whom are employed in clerical departments of my firm. The re-examination, in modified form, of employees on re-engagement on temporary or seasonal staffs should be carried out.

The examination on return from illness is hardly less important. The factory doctor, knowing the nature of the patients' employment, is favourably placed to judge of their fitness to resume work, and it is found that, far from his duties in this respect being a source of friction with the panel medical practitioner, the latter very often sends the employee to the factory doctor before issuing the final certificate of fitness for work. This routine visit of all sick absentees to the clinic on leaving or resuming work acts as a very wholesome check on unnecessary or unduly prolonged absence, and when, as is the case with my firm, the management grants wages, less panel sick benefit, during sickness, in accordance with a scale dependent upon length of service and a satisfactory report on each case from the factory doctor, there is every encouragement for recovery and little opportunity for malingering. It also enables the firm's medical officer to safeguard other employees from the premature return of those suffering from infectious diseases, and this raises the very interesting problem of quarantine of contacts with these diseases. Except in scarlet fever, where there has been close contact with the disease, and the usual period of quarantine is generally advisable, exclusion from work usually appears unnecessary, though one considers whether the contact works in the open or in a room with young and susceptible persons. Variola contacts, with the agreement of the district medical officer of health, are allowed to resume duty after revaccination. Diphtheria contacts, especially if negative throat swabs have been obtained, may generally continue at work, but for a week have the throat examined by the factory nurse each day before commencing duty. Contacts with measles, rubella, varicella, and mumps are allowed to remain at work provided they keep out of the sick room. Public conveyances and cinemas are such prolific sources of infection that the rigid exclusion of contacts from factories appears to me a useless waste of working time, and so far the above measures have never failed to prevent the diseases spreading in the factory. On the other hand, great care is taken in regard to any possible infection from an occasional case of enteric or paratyphoid fever and to detect any carriers of these diseases.

Diagnosis and Treatment of Minor Illness.

"Such medical emergencies enter largely into the work of the clinic. What chiefly is required of the doctor in charge of a factory clinic is a sound general experience of clinical medicine and surgery, the ability to make a prompt diagnosis and to reach quick decisions. He sees a great number of apparently trivial cases among which, at any time, usually when he is most busy, may be one with the early signs or symptoms of a grave condition, such, for instance, as an acute mastoiditis, a perforated duodenal ulcer, strangulated hernia, or an acute appendix. It is no use sending such cases home to the panel doctor, who may be out and unable to see the case for some hours, consequently the factory doctor has to find a bed for them in hospital and arrange for transport there. This is when previous working coöperation with the nearest hospital comes in so useful, and reciprocal arrangements are easily made in view of the fact that the work of the clinic relieves the hospital of so much of its other work, as I will explain shortly. In a large concern the firm must have its own motor ambulance. The medical officer finds that his advice and guidance are sought regarding a multitude of health problems, the answers to which have to be given definitely and often by telephone. He must know which specialist to recommend in any particular case, what days of the week certain departments of hospitals see patients, where beds are available, what to do with a case of mumps, how to disinfect a room, what the various diagnoses on panel certificates really mean, and how long incapacity is likely to last in various complaints. Sometimes he may have to see between 70 and 90 patients in a day, and always he will find the work extremely exacting though full of interest. He has opportunities enjoyed by few of his professional colleagues for preventing avoidable disease, for detecting the earliest signs of impending illness, and for assisting to build up healthy, happy, useful citizens. His knowledge and experience should enable him to estimate the capabilities of the individual worker, to guard him against injustice, and to protect the employer from imposture. His position, moreover, is largely privileged and gives him certain advantages in dealing with refractory patients that are denied to panel or private practitioners, for, unlike them, he can, should occasion arise, be candid without fear of consequent unpopularity."

[Colonel Mummery explained the method in which, under his own particular organisation, while the actual treatment is left to the practitioner or the hospital, a welfare visitor keeps in touch with the patient; but in regard to the treatment of injuries, where he noted the recent increase in figures and mortality, he pointed out the value of treating these at the clinic, where the employee was able to continue his work or lived nearby. He described the facilities furnished at his own clinic, and pointed out that the economy of time thus ensured was a valuable asset in industry. When further assistance than the clinic could render was required he found that the splendid work of the voluntary hospitals too often did not meet the case, and he suggested that another kind of hospital or after-care centre was what the factory clinic should provide, where the remedial work would help the employee and the industrial manager, and the covering insurance companies would be satisfactorily informed.

After commenting on the valuable work that can be done at the industrial clinic in the detection of cutaneous disorders, he continued :—]

Special Treatments at the Industrial Clinic.

"Dental sepsis is responsible for so much ill-health and absenteeism that it is unwise to pass applicants with serious dental caries or pyorrhœa until these conditions have been corrected. It is a sound rule that sick absence due to this cause disqualifies an employee from receiving compassionate financial assistance. The equipment of the dental surgery, consisting of furniture, instruments, and materials, is provided by the firm. At Cadby Hall Clinic we have two part-time dental surgeons giving their services on five days a week. Appointments are made in advance. Treatment includes fillings, scaling, extractions, and provision of dentures. The latter are made in the dentists' own workrooms. All charges are those laid down by the National Health Insurance dental benefit scheme with special terms for those not entitled to that benefit, and extended payments by small weekly deductions from wages are arranged, the firm accepting liability for any bad debts. During 1930 the dental treatments at the clinic numbered 4124.

"An ophthalmic centre is maintained at the clinic for employees. Of recent years many of the National Health Insurance societies have granted ophthalmic benefit to insured persons, sending them to an optician for the correction of errors of refraction. In order to improve upon this arrangement the firm provides the services of a specialist ophthalmic surgeon at the clinic on one evening a week and supplies the spectacles in the orders at a contract price. The firm pays him a salary and collects any panel ophthalmic benefit granted by the society. In other cases time-payment is allowed.

"Massage, radiant heat, high-frequency treatment, and facilities for certain remedial exercises are available at the clinic all day. Great success has attended the treatment here of flat-foot by regular massage and inversion and flexion exercises. Stiff fingers after accidents respond well to the method of pumping coloured water from one bottle to another, and stiff shoulders and arms rapidly regain function with other special forms of exercise. Two fully qualified nurses, holding the certificate of the Chartered Society of Massage, form the staff of this department and also take their turn in the surgery. I have already referred to the value of this work in the factory. During 1930, 2323 massage and remedial treatments were given.

"Manicure is provided free for employees in certain departments of the factory where special cleanliness is desirable or where there is a tendency to the development of cracks or other slight trauma setting up infection—such as among fruit-pickers, who were particularly liable to peri-ungual sepsis before manicure stopped it. Chiropody is available at small charges for the treatment of corns.

"Facilities for consultations with specialists at the firm's expense are available through the medical officer and welfare department, who have made arrangements to that end with consultants in every branch of practice.

Records and Statistics.

"The duty of keeping records concerning the health of the factory staff, and of the incidence of illness and accidents among them, falls upon the welfare department. The staff of the clinic in my medical charge consists of a charge-sister and four other fully trained nurses, two of whom, as already stated, are qualified masseuses. As the work of the factory goes on day and night, one nurse has to be on duty all night, and two are on duty in the surgery during the busier hours of the day. The necessary clerical services, of course, are also provided.

"During 1930, 9995 injuries were treated at the clinic. Of these, 8455 remained at work and 1540, representing 15·4 per cent., were put off duty; 12,748 re-dressings were done, 11,538 of these were during the continuance of employment, and 1210, representing 9·5 per cent., while away from work; there were 2255 attendances of skin cases of all kinds, 1797 of these while at work, and 458, representing 20·3 per cent., during absence from work. (In this connexion I must state that I insist upon a short absence from work in all acute skin diseases because I find it considerably shortens the duration of the complaint and ultimately saves lost time.) 12,258 cases of illness were seen and treated; 9446 of these remained at work, and 2812, representing 23 per cent., were sent home; 2415 persons were medically examined for employment; 1033 patients from outlying hotels, corner houses, and tea shops were seen in consultation.

"I have tabulated the various causes of absenteeism amongst the factory operatives during 1930, showing the number of cases amongst males and females, respectively, the lost time, and the average duration of absence in each case. It should be noted that amongst these operatives the males exceed the females in number by about 2000. My table shows that acute respiratory diseases account for the largest number of cases affecting the sexes fairly equally, there being 1157 cases in all, with a total of 12,510 lost days, giving an average of 11 days per case. Acute gastritis and gastro-enteritis come next in frequency, affecting females much more than males, with a total of 504 cases and 4615 total days lost, giving an average of nine days per case. Fibrositis was more prevalent amongst the males, the total number of cases being 261, and the total days lost 4368, with an average of 17 days per case. Diseases of the ear, nose, and throat were more common amongst the females, with a total of 265 cases, and 3189 lost days, giving an average of 12 days per case. Furunculosis was about three times as common among the males as among the females. There were 128 cases and 1648 lost days, with an average of 13 days per case. Neuritis predominated among the females, but the males, on account of the larger incidence of lumbago and sciatica among them, were longer away from work than the females. The latter, on the other hand, suffered more from brachial neuritis, which, however, cleared up more quickly. There were 106 total cases, with 1058 days lost, and an average of 10 days per case. Genito-urinary diseases were almost entirely confined to females. Tubular disease, uterine displacement, and true dysmenorrhœa accounted for most of the cases, the total number of which was 197, and the total days lost 1345, giving an average of seven days per case. Very few cases of venereal disease in either sex occurred. Taking into account the number of males and females employed as factory operatives, the incidence of accidental injuries was fairly equally distributed between the sexes, and the average of 13 lost days per case from this cause compares favourably with published statistics.

Conclusions.

"At the beginning of this lecture I mentioned that Sir George Newman's report showed that the insured population of England and Wales lost on an average 3·73 weeks working time per annum, and Sir Thomas Oliver (*Journal of State Medicine*, August, 1930) states that during the past 30 years the length of sickness has increased from 16½ days to 28 days. It is interesting to compare with these figures for the insured population of the country as a whole those of my clinic, which are as follows. The factory staff lost on an average 13 working days each in 1929 and eight days each in 1930. The average duration of absence on account of illness in 1929 was 15 days, and in 1930 it was 12·7 days. The average duration of absence on account of injuries in 1929 was 13·3 days, and in 1930 it was 13 days.

"The clinic I have been referring to is the chief clinic of a very large firm with a factory and clerical staff numbering 6132, and, in addition, the clinic serves in some degree also the firm's 30,000 employees scattered throughout London. It even serves to some extent numerous other employees in the provinces, and even in Ireland, for travellers and motor drivers are sent for examination on engagement, and special cases may be sent to Cadby Hall Clinic for assistance. The organisation is not necessarily applicable to other firms. I have outlined, however, a scheme of services which can be modified to meet most needs, and have laid special stress on those which have proved most valuable both to employer and employee. For the past seven years, during which time the present welfare organisation of my firm has been built up, I have been able to watch the steady improvement in the health and general condition of its employees. As the attendances at the factory surgery have increased, the absenteeism has decreased; with much better dental hygiene the incidence of gastritis, lumbago, and other varieties of fibrositis has fallen; and, whereas in the early days pediculi and other human parasites were not infrequently seen, they are now only conspicuous by their absence. The crying need of industry to-day, however, is for some means of controlling effectually the common complaints, such as epidemic nasal catarrh, bronchitis, epidemic influenza, and rheumatism, which together are responsible for so much absenteeism and are so serious a burden on industry. Yet, like many others, I have carried out extensive and carefully controlled experiments with vaccines and nasopharyngeal prophylaxis in an attempt to reduce the incidence of epidemic coryza, but with entirely negative results; and furunculosis, lacking as it does any common causative factor, is also at present outside the scope of our preventive methods."

THE DRESDEN HYGIENE MUSEUM.

ALTHOUGH a beginning has been made in this country in the provision of museums for teaching hygiene to the public, these as a rule are parts of other buildings not specially designed for the purpose. The Dresden Hygiene Museum has lately been given a home of its own, which is described in the *Museums Journal* for July. The building stands well away from others in a beautiful situation in the heart of Dresden. The plans of the architect, Prof. W. Kreis, provide well-lighted corridors running through the whole museum; the exhibits are almost all placed in rooms on the outer side of the building; these are lit by top-side windows. Monotony has been avoided by giving each of these rooms an individual shape and colour and by using different materials for flooring and walls. For the visitors a rest room, refreshment room, and roof garden are provided. Roughly, half the area of the building is devoted to exhibits; the other is given over to ancillary purposes, workshops and packing rooms, bookshelves, laboratories, store rooms, and a gymnasium. Much help is afforded in the teaching of hygiene outside the museum. In the workshops material for teaching is made; this includes, besides the ordinary anatomical and biological diagrams, posters, lantern slides, and especially casts. These models are almost unbreakable; they can be washed, and are not affected by changes of temperature, and, owing to mass production, are considerably cheaper than wax models. Travelling exhibitions are organised. These have been shown widely over Europe, and a special motor-car has been fitted for smaller exhibitions in the lesser towns and villages. Another section produces its own films. In the same building is the Academy of Hygiene, the head of which is Prof. Weisbach, in which teachers of hygiene are trained.

Three million people visited the International Hygiene Exhibition in Dresden last year. The exhibition has been repeated this year, and will go on to the end of September.

HOLIDAYS FOR WORKING WOMEN.

THE following letter reaches us from the offices of the Women's Holiday Fund:—

"May we again appeal on behalf of the working women of London for the generous help of those of your readers who are now enjoying, or about to enjoy, their own holidays? Of all who toil hardest year in, year out, the working-class mother holds the foremost place. Her labours are never done, and in her self-sacrificing life there is little room for any sort of recreation. A holiday means to her not only respite from work but often restoration to health, and it is in consequence a necessity rather than a luxury. Last year the Women's Holiday Fund (founded in 1895) sent away 1154 women and 640 children. Whether or no the same number can be helped this year depends largely on the result of this appeal. The women pay as much as they can afford towards the cost of the fortnight's holiday, many of them putting by a few pence each week in order to do so. Donations, large or small, will be most gratefully received by the Secretary of the Fund, 76, Denison House, Vauxhall Bridge-road, London, S.W.1."

The appeal is signed by Lady Maud Carnegie, the Bishop of London, the Rev. F. C. Devas, S.J., the Rev. J. Scott Lidgett, Sir George Blacker, F.R.C.P., and Mrs. Frank Pownall (Chairman of Executive Committee).

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

PADDINGTON MEDICAL SOCIETY.

The next meeting will be held on TUESDAY, July 14th, 9 P.M. (at the Great Western Royal Hotel, Paddingto W.): Discussion on Maternal Mortality, to be ope by Dr. G. E. Oates, Mr. T. G. Stevens, and Dr. Leon Colebrook.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE, 1, Wimpole-street, W.

MONDAY, July 13th to SATURDAY, July 18th.—PRIN OF WALES'S HOSPITAL, Tottenham, N.15. Seco week of post-graduate course in general medicine a surgery. Daily 10.30 A.M. to 5.30 P.M., demonstrati lectures, operations.—Further particulars from Fellowship of Medicine.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.

MONDAY, July 13th.—10 A.M., Gynæcological Ward Visit Genito-Urinary Operations, Skin Department. 11 A.M. Surgical Ward Visit. 2 P.M., Surgical Ward Visit Medical, Surgical, Eye, Gynæcological Out-patients

TUESDAY.—9.30 A.M., Operations. 10 A.M., Medical Ward Visit, Dental Department. 11 A.M., Throat Operations 11.30 A.M., Surgical Clinical Demonstrations. 2 P.M. Medical, Surgical, Throat, Out-patients, Operations Medical Ward Visit.

WEDNESDAY.—10 A.M., Medical Ward Visit, Children's Medical Out-patients. 2 P.M., Medical, Surgical and Eye Out-patients. Gynæcological Operations. 4.45 P.M., Venereal Diseases.

THURSDAY.—10 A.M., Neurological Department. 11.30 A.M. Treatment of Fractures. 2 P.M., Medical, Surgical, and Eye Out-patients. Genito-Urinary Department, Operations.

FRIDAY.—10 A.M., Medical Ward Visit, Skin and Dental Departments. 12 noon, Medical Lecture. 2 P.M. Medical, Surgical, and Throat Out-patients. Operations.

SATURDAY.—9 A.M., Throat Operations. 10 A.M., Medical Ward Visit, Surgical and Children's Medical Out-patients.

CHARING CROSS HOSPITAL MEDICAL SCHOOL POST-GRADUATE COURSE.

SUNDAY, July 12th.—10.45 A.M., Dr. R. A. Hickling: The Investigation and Treatment of Cases of Severe Anæmia. 11.45 A.M., Dr. H. G. Everard Williams: Physiological Principles in Gynæcology.

ST. MARK'S HOSPITAL, City-road, E.C.

THURSDAY, July 16th.—4.30 P.M., Sir Charles Gordon-Watson: Carcinoma of the Colon.

UNIVERSITY OF BIRMINGHAM.

TUESDAY, July 14th.—3.30 P.M. (at the Children's Hospital), Prof. Parsons: Demonstration of Cases of Children's Diseases.

FRIDAY (at the Queen's Hospital).—3.30 P.M., Dr. J. F. Brailsford: X ray Investigation of Alimentary Canal.

ADDRESSES AND ORIGINAL ARTICLES

TOXIC JAUNDICE.[*]

BY SIR WILLIAM WILLCOX, K.C.I.E., C.B., C.M.G., M.D., F.R.C.P. LOND.,
PHYSICIAN TO ST. MARY'S HOSPITAL.

LECTURE III.

THERE is no variety of toxic jaundice produced by known chemical exogenous poisons for which an exact counterpart may not occur from biological toxins, and the converse is also true. The morbid anatomical and histological changes in the liver may be precisely the same under the two conditions. The bacterial infection may be that of a micro-organism the characters of which are generally accepted as specific or from one of a group of organisms, such as the streptococcal group, the specificity of which is indefinite.

Enteric Group Disease.

Typhoid Fever.—Jaundice is well recognised as a complication of this disease. Osler[35] quotes from his series of 1500 cases the occurrence of jaundice as 0·5 per cent. and that of cholecystitis as 1·3 per cent. In the epidemics of typhoid fever which occurred in the East during the late war jaundice was certainly more frequent than this. Usually the jaundice occurred during the height of the fever, and resembled in its course that of epidemic catarrhal jaundice superadded to the typhoid fever attack; its presence did not seem to add seriously to the gravity of the prognosis unless it was associated with acute cholecystitis.

The cause of the jaundice appears often to be an ascending infection, causing catarrhal inflammation of the intrahepatic bile-ducts, though no doubt the liver cells may be acted upon directly by the toxins in the circulation and jaundice arise thereby.

A case of typhoid under my care in March, 1931, is of interest.

CASE 27.—Mr. X, onset Feb. 5th, 1931. Temperature 103°F. *B. typhosus* was found in the blood on Feb. 7th and 11th. The case ran the usual course of an acute typhoid attack. On Feb. 18th an acute attack of abdominal pain occurred, associated with sudden collapse and drop of temperature to 97°; the clinical symptoms resembled those of intestinal perforation. On examination of the abdomen no signs of peritonitis were found, but the gall-bladder could be felt projecting forwards like a distended sausage skin. Sir Crisp English saw this case with me and confirmed the diagnosis. Hypodermic administration of atropine and local fomentations were followed by a rapid disappearance of the symptoms, of which there has been no recurrence.

Paratyphoid Fevers A and B.—These diseases were extremely common during the Dardanelles and Mesopotamian campaigns. Jaundice was comparatively frequent, probably occurring in more than 5 per cent. In fact, so frequent was it that some observers suggested that epidemic catarrhal jaundice was due to paratyphoid infection, but this assumption was not borne out by the bacteriological investigations. Jaundice occurred in both paratyphoid A and B cases.

In enteric and paratyphoid fever the commonest time of onset is towards the end of the second week. I have, however, seen cases, the diagnosis of which was confirmed by positive blood culture, in which jaundice occurred within the first six days, and in a few it was present at the onset of the symptoms. In one case it did not occur until the twenty-ninth day of the disease.

CASE 28.—One case seen by me in 1915 in the Dardanelles was under the care of Captain C. H. Corbett, R.A.M.C. The patient developed jaundice on the third day after admission to hospital, and death occurred six days later from sudden collapse. At the post-mortem examination the mucous membrane of the duodenum was found to have a red velvet appearance, and the walls of the common bile-duct and hepatic ducts showed acute inflammation; the gall-bladder was distended with semi-purulent greenish bile which contained paratyphoid B organisms.

I have seen toxic jaundice in more than one case during the severe febrile reaction lasting several days which followed a full dose of prophylactic typhoid vaccine. This shows that a blood-borne toxic jaundice may follow typhoid infections, quite apart from an ascending inflammation by the bile-ducts.

Parenteric Infections.—A group of non-lactose fermenting coliform bacilli very closely resembling the typhoid bacillus but differing from it in certain sugar-fermenting reactions and in serum agglutination tests is included in this group. Examples are: *B. asiaticus* and *pseudo asiaticus*, *B. fæcalis alkaligenes* and *pseudo-fæcalis alkaligenes*, the bacillus of epidemic jaundice, and Morgan's bacillus. These organisms may give rise to an acute illness closely resembling typhoid fever clinically, the organisms being found in the blood, the stools, and urine. In 1917 in Mesopotamia an outbreak of illness presenting the clinical symptoms of typhoid occurred in five members of a mess. Those cases which were seen by me, were fully investigated bacteriologically by Lieut.-Colonel F. P. Mackie, I.M.S., and the organism found responsible for them was *B. fæcalis alkaligenes.* Similar outbreaks due to *B. asiaticus* have occurred in Egypt. I have met with many cases of illness of a typhoid-like character where the bacteriological findings have confirmed the presence of one or other of this group of organisms as the causal agent.

The illness "parenteric fever" usually runs a much shorter course than typhoid and is not associated with the symptoms of intestinal ulceration though the characteristic spots and enlargement of the spleen are commonly observed and jaundice may occur.

This group of organisms is often associated with abdominal symptoms of a chronic or subacute type, such as jaundice, cholecystitis, enteritis, colitis, and hepatitis. Attention was called to parenteric infections in a paper published by me in June, 1927.[36] Numerous cases of chronic toxic jaundice have been under my care where the bacteriological examination of the stools has shown the presence of one of this group of organisms and where a definite serum agglutination reaction of high value has been given.

CASE 29.—A medical man under my care at St. Mary's Hospital in 1928 had been for a holiday in France and returned with jaundice of a mild toxic type. *B. asiaticus* was found in the stools and a serum agglutination reaction of 1 in 250 was given to the organism found.

I am fully aware that organisms of the parenteric group are very commonly found in the stools of persons who have been abroad, especially in tropical countries, and that these organisms may exist apart from any symptoms of illness; in other words, "carriers" are comparatively common. The conclusion that a member of this group is responsible for jaundice in a given case must not be arrived at hastily. These infections may cause an alteration in the agglutination reaction to typhoid or paratyphoid A and B, and so may lead to the incorrect assumption that enteric group disease is present. I have come to the conclusion that agglutination reactions alone are of little or no value in making a diagnosis of enteric group disease; they must be confirmed by other findings, such as blood culture, the presence of the organisms in the excreta, and leucopenia.

---

[*] The Lumleian Lectures delivered before the Royal College of Physicians of London on March 19th, 24th, and 26th, 1931. Lectures I. and II. appeared in THE LANCET of July 4th and 11th respectively.

In some cases of chronic toxic jaundice of intestinal origin *B. coli communis* may play a causative part.

CASE 30.—A man, aged 46, was seen on Sept. 19th, 1930. He gave a history of liver attacks every few months for 20 years, often associated with mild jaundice for some days, and discomfort in the right hypochondrium, but no actual pain. The liver was enlarged and smooth, reaching 2 inches below the subcostal border in the right nipple line. There was no history of alcoholism or syphilis, and the Wassermann reaction was negative. Radiography of the gall-bladder after tetraiodophenolphthalein showed nothing abnormal. Bacteriological examination of the stools by Dr. A. Fleming showed hæmolytic and non-hæmolytic *B. coli*, the latter giving a positive agglutination reaction with the serum of 1 in 120. The toxic jaundice was apparently due to this infection.

In this case the administration of alkalis, liver extract, and glucose, and inoculations with an autogenous *B. coli* vaccine, have been followed by a complete disappearance of the symptoms and signs.

Food-poisoning Organisms.—These are closely allied, morphologically and culturally, with the parenteric group of organisms. Clinically they are entirely different, for they give rise to acute enteritis, the latent period of the symptoms being very short: a few hours up to three or four days. The organisms are known as the "salmonella group," and the two chief are *B. aertrycke*, of which there are many strains, and *B. enteritidis* (Gaertner's bacillus), of which many strains have been described. Occasionally the dysentery bacilli, such as the bacillus of Shiga or of Flexner, may give rise to acute food poisoning.[37] Food-poisoning infections are not infrequently associated with toxic jaundice, a typical case of which is the following.

CASE 31.—A man, aged 40, was seen by me in consultation with Dr. A. H. Thomas on July 26th, 1928. He had enjoyed fairly good health, and had been accustomed to take alcohol fairly freely but not to excess. Two teeth has been removed on July 17th, after which somewhat unusual bleeding had occurred, but not sufficient to require medical attention. On July 19th he had eaten a ham sandwich at a restaurant. He had thought this was not good, and shortly afterwards had experienced nausea and abdominal discomfort. On July 20th he had consulted Dr. Thomas, and his temperature had been 99° F. On July 23rd a macular rash had appeared on his chest. On July 25th he had slight jaundice and a temperature of 100°. Diarrhœa and pyrexia continued. On July 26th he was drowsy, delirious, and incontinent of fæces and urine, and showed ptosis of the eyelids. This patient was also seen by Dr. Geoffrey Evans and the clinical diagnosis of food poisoning was made. Bacteriological examination of the stools showed an infection with one of the salmonella group. The patient died on July 27th from symptoms of hypohepatism and toxæmia.

The case was reported to the coroner. Post-mortem examination by Dr. Newcomb showed acute gastro-enteritis. The liver was large, pale, and flabby, and showed marked fatty degeneration. Cloudy swelling of the kidneys and suprarenals was present. Cultures from the spleen showed a marked infection with one of the salmonella group of organisms.

In this case the cause of death was acute food poisoning; possibly the toxæmia associated with the dental extractions and the history of moderate excess of alcohol were contributing factors. A point of interest in the case was that at the time of the illness numerous cases of food poisoning from infected ham had occurred in London, several of them in the police force.

Influenza.—The occurrence of jaundice in influenza, especially in the gastro-intestinal type, has been long recognised. Epidemics vary greatly as regards the occurrence of jaundice; in some it may be relatively common, but usually it is absent or very rare. Sir Wilmot Herringham in 1919[38] pointed out that in the epidemic of influenza in March, 1919, jaundice became for the first time a fairly frequent symptom.

Pneumonia.—Jaundice, like influenza, occurs with irregularity in outbreaks of pneumonia; usually it is rare, but in some outbreaks it may be not uncommon. It is usually of toxic type and due to the action of the pneumonia toxins in the liver cells.[39]

Streptococcal Infections.—Toxic jaundice has been observed on many occasions during the acute streptococcal infection associated with tonsillitis or sinus inflammation in the nasopharynx, and in cases of dental infection.[40] In acute streptococcal septicæmia toxic jaundice sometimes occurs, owing to the action of the circulating toxins on the liver cells. The jaundice of streptococcal infections is sometimes of the hæmolytic type, and then an indirect van den Bergh reaction is given. The following two cases are illustrative.

CASE 32.—A man, aged 57, gave a history of recurring gout for years. "Influenzal attacks" often occurred two or three times a year. He had been treated for flatulence and dyspepsia from time to time for the last year. From May 20th to May 22nd, 1927, he had malaise and fatigue. On May 23rd his temperature was 100° and he had jaundice. On May 27th he developed pneumonia in the middle and lower lobes of the right lung, and the jaundice was more marked. Bacteriological examinations by Dr. John Freeman showed a streptococcal infection in the sputum and stools. The Wassermann reaction was negative. On June 2nd the van den Bergh test showed a very marked biphasic reaction. The icterus index was 150 and the blood-urea 134 mg. per 100 c.cm. The urine had a specific gravity of 1020 and a urea content of 2 per cent. It showed a cloud of albumin and large numbers of granular and epithelial cases. Bile-pigments and bile-salts were present. The stools were clay-coloured.

This patient was also seen by Sir Humphry Rolleston and Sir John Rose Bradford, who confirmed the diagnosis of toxic jaundice. On June 5th there were some delirium and muscular twitchings, and the symptoms of acute hypohepatism (icterus gravis) gradually developed in spite of all treatment. Death occurred on June 11th.

In this case the symptoms of toxic jaundice due to necrosis of the liver were combined with those of uræmia due to the poisoned kidneys.

CASE 33.—A married woman, aged 52, with three children, was under the care of Dr. Hugh C. Wilson. In December, 1920, a gastro-jejunostomy was performed for a dilated duodenum, but no ulcer was found. In August, 1921, laparotomy was performed for adhesions. At a subsequent laparotomy in December the gastro-jejunostomy opening was closed and an anastomosis was made between the duodenum and jejunum. In July, 1922, anæmia developed. In September, 1923, the remaining teeth were removed. The patient was first seen by me on Jan. 22nd, 1924. She was suffering from recurring attacks of abdominal discomfort associated with colon spasm and the passage of much mucus. These attacks were accompanied by mild jaundice with hepatic discomfort and an increase in the anæmia. On Feb. 1st, 1924, bacteriological examinations by Dr. A. Fleming showed a marked intestinal infection with *Streptococcus viridans*. The blood picture was typical of pernicious anæmia. A blood transfusion was given on Feb. 2nd. In view of the recurring attacks of abdominal pain the abdomen was opened on Sept. 11th; numerous adhesions were found and a dilated gall-bladder, with one very small stone which was playing no part in the causation of the symptoms. The patient died two days after the operation, internal hæmorrhage resulting, as so often happens after operation in cases of toxic jaundice.

In this case the recurring attacks of toxic jaundice and hepatitis appeared to be due to the streptococcal bowel infection.

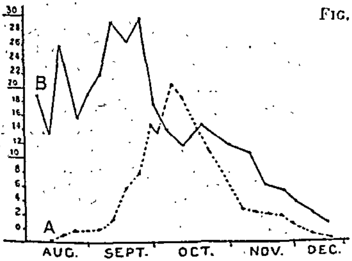
Staphylococcal infections, if of an acute or subacute type, have been associated with toxic jaundice.

Epidemic Catarrhal Jaundice.

This disease occurred with great frequency during the late war. It was most common in those areas where intestinal disease was most rife, for example in the Dardanelles and Mesopotamia. It was generally of a mild type and clinically similar to the cases of ordinary catarrhal jaundice met with in this country; in fact, the diseases are, in my opinion, identical. Gunson and Gunn published [41] an interesting account of a series of cases occurring in British troops at Alexandria in 1915, and I published an account of the epidemic jaundice in the Dardanelles.[42] [49] In 1916 Archibald, Hadfield, Logan and Campbell [43] described their careful work in the Mudros laboratories on the Dardanelles cases, while Martin [44] published an account of the pathology and ætiology of the disease.

An interesting account of a recent epidemic in Yorkshire was published by Pickles.[45] A Ministry of Health report on an outbreak of 200 cases was published in 1927 [46]; in this epidemic there was one death.

FIG. 4.



Incidence rate of epidemic jaundice and diarrhœal diseases in the Dardanelles per 1000 troops in one Division from August 7th to Dec. 19th, 1915. A = jaundice. B = diarrhœal diseases (diarrhœa, enteritis, and dysentery).

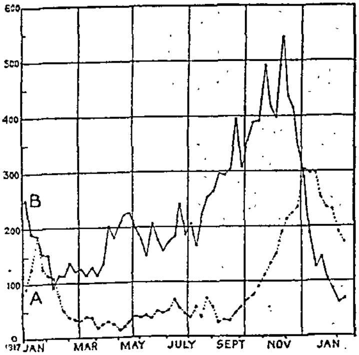
Epidemic catarrhal jaundice is not a new disease. In the American War 22,509 cases occurred, with a mortality of 161, or 0·71 per cent.; in the South African War 5648 cases occurred with a small mortality.

Ætiology.—Bacteriological investigations have, up to the present, failed to identify any specific organism. In some cases coliform organisms of the *B. coli communis* or *B. fæcalis alkaligenes* type have been found. It seems probable that the disease is caused by a catarrhal condition of the duodenum and bile-ducts set up by organisms which are found in health in the intestinal tract. In this way the disease resembles the common "cold in the head," which may be set up by many different catarrhal organisms which are commonly present in the nasal passages in conditions of health.

The disease, like typhoid, does not appear to be contagious from person to person, though many people may become infected from a common cause. The war experience indicates that the alimentary tract is the channel of infection. This is well illustrated by a comparison of the curves (Fig. 4) for epidemic jaundice and diarrhœal diseases in the Dardanelles and Mesopotamia. Pickles suggested that the infection might be air-borne, but this view does not agree with war experience. The disease often occurs in epidemics, but sporadic cases of an identical disease are commonly met with in ordinary medical practice.

Mortality.—In 1917 the Mesopotamian records showed that in British troops the mortality from 1538 cases was 0·6 per cent., while in Indian troops the mortality out of 2633 cases was 0·3 per cent., the gross mortality being 0·41 per cent.

Symptoms.—Usually there is a premonitory period of a few days, associated with nausea and perhaps some occasional vomiting, abdominal discomfort, and diarrhœa; or constipation may be present. The temperature is normal during this period. Pyrexia, usually of a mild type, now sets in, accompanied by chilliness and occasionally shivering; the tongue is moist and often furred. Nausea and vomiting sometimes occur at the onset of the pyrexia, also headache and general pains may be present. Acute abdominal pain is absent, but there is usually some discomfort in the hepatic and epigastric regions. The pyrexial period usually lasts for from two to four days.



Incidence rate of epidemic jaundice and dysentery in Mesopotamia for 1917–18. A = jaundice. B = dysentery.

Jaundice generally appears about the third or fourth day from the onset of the pyrexia. It gradually deepens and becomes of the ordinary obstructive type, with putty-coloured stools and bile-containing urine. It attains its maximum in about ten days and then gradually subsides. It is important to realise that the pyrexial period may sometimes be prolonged (Fig. 5); I have seen it last for 14 days. Also the jaundice may persist for several weeks, even as long as ten weeks, ultimately clearing up. Unless this is realised there is risk of an unnecessary surgical operation on these cases on the assumption that there is obstruction of the common bile-duct. As already pointed out, a surgical operation on a case of toxic jaundice is associated with danger, and fatal hæmorrhage not infrequently results.

In catarrhal jaundice the liver shows a considerable uniform enlargement and is slightly tender up to the time that the jaundice begins to subside and the stools resume their normal colour. It then gradually returns to its normal size. As a rule the gall-bladder cannot be felt, though in a small proportion of cases—about 10 per cent.—it appears to be enlarged. The spleen is enlarged in the early stages of the illness and can be felt extending below the left subcostal border for half an inch or more for a few days from the onset of the pyrexial period. The enlargement quickly subsides.

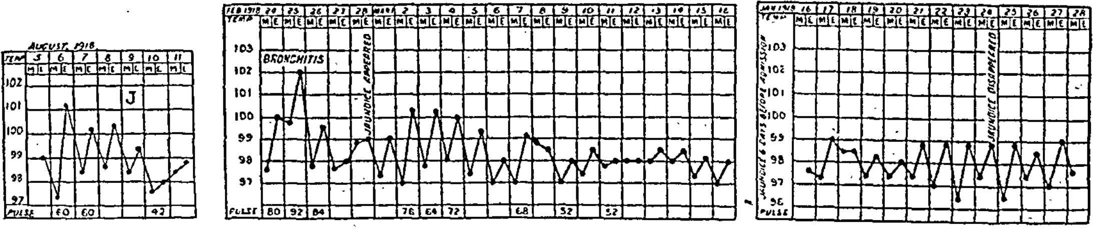
A curious and constant feature of catarrhal jaundice is the definite increase in the deep cardiac dullness in the fourth intercostal space to the right of the sternum. This dullness may extend for an inch or more to the right of the sternal border, and corresponds to a dilatation of the right auricle. There is usually no sign of dyspnœa or cardiac distress, and it seems likely that the increased dullness may be due to a tilting upwards of the heart by the enlarged liver and spleen. X ray examinations should clear up this point.

Usually cases of catarrhal jaundice give rise to no anxiety, but a cautious prognosis should be given, since it is known that fatal symptoms of hypohepatism due to necrosis of the liver occur in from ½ to 1 per cent. of cases. Catarrhal jaundice demands careful treatment and should not be lightly regarded. Rest in bed till the jaundice subsides and a careful diet régime are indicated. Lack of care in treatment increases the risk of necrosis of the liver cells or of the development of a chronic progressive hepatitis.

HYPOHEPATISM AND NECROSIS OF THE LIVER IN CATARRHAL JAUNDICE.

The symptoms of this grave condition have already been described. They usually begin about ten days after the appearance of the jaundice, but in one case they occurred on the second day, in another the fourth day, and in a third the twenty-fifth day afterwards. There appears to be no relation between the depth of the jaundice and the frequency of occurrence of this grave complication. Some cases were not deeply jaundiced at the time of the onset of the symptoms of hepatic failure; also the preliminary symptoms of the illness were exactly like those of the ordinary type of the disease and gave no warning of the future grave development.

FIG. 5.



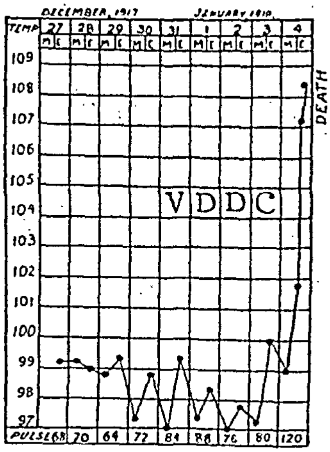
Three cases of epidemic catarrhal jaundice. In the first chart J = time of appearance of jaundice. In the third chart jaundice appeared six days before admission.

One case out of a considerable number of which I have notes might be quoted (Fig. 6).

CASE 34.—Lieut. A. was taken ill on Dec. 24th, 1917, with slight fever and the usual symptoms of epidemic catarrhal jaundice On Dec. 28th his temperature was normal, his liver enlarged and tender, his spleen palpable and slightly tender, and his tongue furred; definite jaundice was now present. The bowels were constipated and the urine bile-stained. The mental condition was normal.

Several attacks of vomiting occurred from Dec. 29th to Jan. 1st, 1918. On Jan. 2nd the vomit contained streaks of blood and was bile-stained. The jaundice was now deep. Restlessness and delirium began during the early morning and throughout the day. On Jan. 3rd he vomited blood-stained material and had epistaxis. The liver dullness was now much diminished, being only two inches vertically in the right anterior axillary line. The patient was very restless and noisy, and his knee-jerks were increased. On Jan. 4th he became comatose in the morning. The urine contained albumin and bile and a few red corpuscles. No spirochætes were present in urine or blood. At 5 P.M. Cheyne-Stokes' respiration appeared, and the plantar reflexes were extensor. At 10 P.M. the temperature suddenly rose to 109°, and death occurred at 10.30 P.M.

FIG. 6 (Case 34).



Epidemic catarrhal jaundice with icterus gravis. Jaundice before admission. V = vomited. D = delirious. C = coma. Post-mortem, "Acute yellow atrophy."

Post-mortem examination by Lieut.-Colonel J. C. G. Ledingham, R.A.M.C., and Major T. Y. Gloster, I.M.S., showed: liver 39½ oz. and stained yellow. Spleen enlarged and soft, kidneys yellowish, small hæmorrhages in the pleura, pericardium, omentum, mesentery, and lungs. The mucous membranes of stomach and duodenum contained petechiæ and the contents were blood-stained.

Microscopical examination showed that there was almost complete destruction of the hepatic cells in blocks; only isolated islets of cells remained. In parts there was total necrosis of all but the trabecular tissue. The kidneys showed extensive degeneration of the tubular cells, and the pancreas early but definite cell necrosis, with shrinkage and loss of outline of the cells that remained; in some places there was a great reduction in the number of cells.

Microscopical examination and animal experiments were specially made for the detection of spirochætes, but were entirely negative.

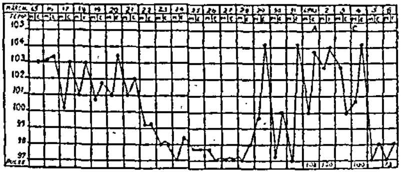
The conclusion arrived at from a study of the clinical symptoms of the disease and from the post-mortem results of a considerable number of fatal cases was that in the majority of cases there was an ascending catarrh of the bile-ducts, leading to a temporary obstruction which was usually intrahepatic. In the more serious cases there was, in addition, a marked degeneration of the hepatic cells which in the fatal cases went on to complete necrosis.

Protozoal Poisons.

Syphilis.—The occurrence of jaundice in this disease is so well known as to need only brief mention. In the acute secondary stage jaundice may be due to the general syphilitic hepatitis accompanied by catarrh of the smaller bile-ducts. In congenital and tertiary syphilis the hepatic fibrosis, whether unilobular, multilobular, or in gross patches forming gummata or scars, is often associated with jaundice.

Relapsing Fever (Figs. 7 and 8).—This disease, due to a blood infection with the spirochæte of Obermeier, is often associated with jaundice.[19] The jaundice occurs quite early, often on the second or third day, and is usually well marked. Captain M. A. Nicholson, I.M.S., from a careful examination of 241 cases in the Isolation Hospital in Bagdad in 1917, found jaundice present in 64 per cent. of cases. The pathology of the condition is analogous to that of the jaundice in secondary syphilis, and the general hepatitis set up by the spirochætes appears to be responsible. Hepatic necrosis rarely occurs.

FIG. 7.

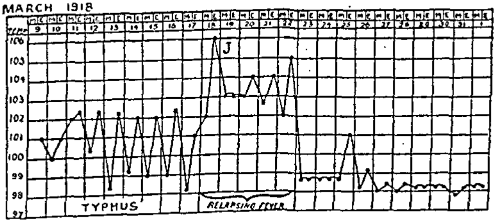


Relapsing fever (Indian), six days' apyrexia. A = blood positive to spirochætes. C = salvarsan 0·3.

Yellow Fever.—In this disease marked cellular necrosis occurs in the liver, often in association with jaundice. The depth of the jaundice is no criterion of the severity of the disease, for it may be slight in the fatal and intense in the less severe cases. Hypohepatism plays an important part in the causation of the grave symptoms. The van den Bergh reaction in cases with marked jaundice was shown by Aitken and Smith[47] to give positive direct results.

Spirochætosis Ictero-hæmorrhagica.—This disease is regarded by Rolleston and McNee as identical with the disease formerly known as Weil's disease. The symptomatology and pathology are quite distinct from that of epidemic catarrhal jaundice, with which there was some confusion during the war. In a report by the Medical Research Council on spirochætal jaundice (No. 113) reference is made to outbreaks which have occurred in Scotland and England. Jaundice, as pointed out by Stokes, Ryle, and Tytler,[48] is not a constant feature of the disease, being present only in 74 per cent. of cases. The van den Bergh reaction is biphasic. The liver does not show the extreme degree of hepatic necrosis found in severe toxic jaundice. When necrosis occurs the destruction of hepatic cells does not appear to be in bulk but is patchy. Fatty degeneration of the liver cells is not a marked feature.

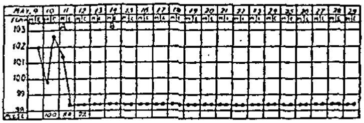
FIG. 8.



Typhus fever and relapsing fever (Arab). J = jaundice.

Malaria (Figs. 9 and 10).—The marked action of the malarial parasite on the red blood corpuscles leads to hepatic and splenic enlargement and anæmia. The hepatitis resulting from a malarial infection is often associated with jaundice, and this is especially so when the infection is of the malignant type. The part played by anoxæmia of the liver cells in the development of jaundice has been already mentioned. For this reason jaundice is much more likely to occur in a patient suffering from a malarial infection when marked anæmia is also present. The liver cells do not suffer the extreme damage and necrosis so commonly seen in toxic jaundice, and as a consequence the development of symptoms of acute hypohepatism is uncommon.

An interesting epidemic of jaundice associated with malaria was investigated by me in September, 1918. At that time a large percentage of the British troops in Northern Persia were infected with malaria and the infection had remained dormant until the influenza epidemic had spread to this region. Towards the end of September many men were attacked by influenza, and this infection stimulated the latent malarial infection into activity, so that the short pyrexial period of the influenzal attack was succeeded or accompanied by the high fever and characteristic symptoms of acute malaria. The liver and spleen were considerably enlarged in a high percentage of these cases, and marked jaundice was a very common symptom. Major C. Christie, R.A.M.C., examined the blood in a large number of these cases and confirmed the diagnosis. He found that in 40 per cent. of the cases of malaria and influenza the parasites were of the malignant tertian type. The combination of the malarial toxins with those of influenza was no doubt the cause of the *intense toxic action* on the liver and of the resulting unusually high incidence of jaundice.



Relapsing fever (Arab). A = blood positive to spirochætes. B = salvarsan 0·3 g.

Blackwater Fever.—A type of malaria associated with intense destruction of the red blood corpuscles and hæmoglobinuria is commonly associated with early jaundice of toxic type. The anoxæmia caused by the severe anæmia is an important added ætiological factor.

Amœbic Dysentery.—The hepatitis so well known to be associated with this infection is frequently associated with jaundice of intrahepatic type.

Typhus Fever.—Jaundice is a rare complication of this disease and was only seen by me in two out of several hundred cases in Mesopotamia.

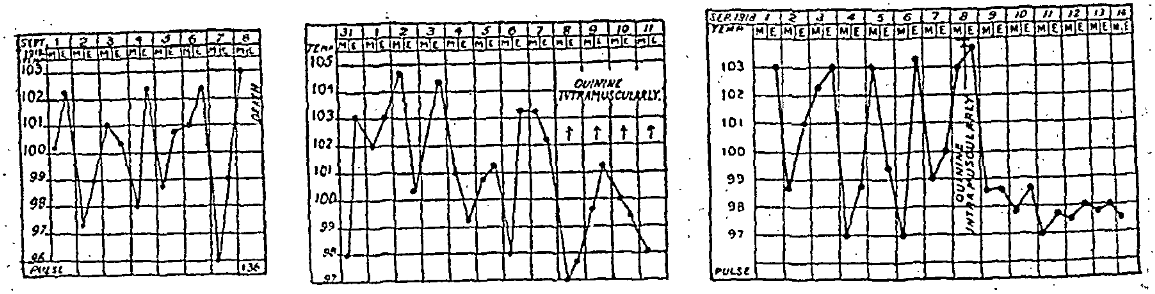
Kala-azar.—This disease, due to the blood infection with leishmanial parasites, is associated with anæmia, *enlargement of the liver and spleen, and prolonged pyrexia.* Jaundice as a result of the hepatitis and blood destruction is a fairly common symptom.

Auto-intoxication.

The Toxæmias of Pregnancy.—These little-understood conditions are manifestations of grave toxæmias of autogenous origin. Intense fatty degeneration and necrosis of the liver is not uncommon, and symptoms of acute hypohepatism, often associated with jaundice, are not infrequent complications.

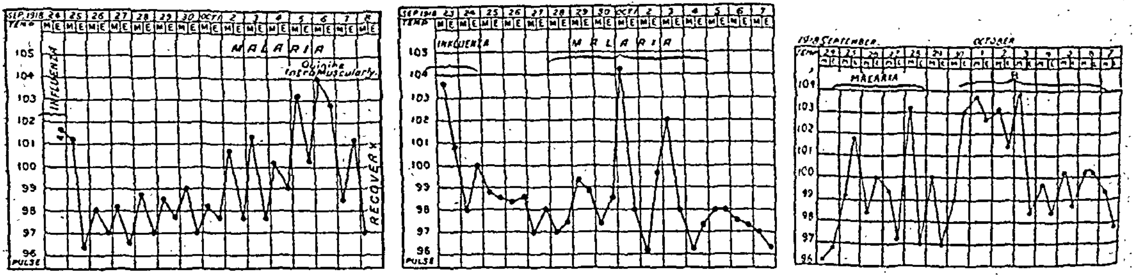
Recurrent Vomiting (Acidosis) in Children.—This condition has been commonly attributed to acidosis and associated ketonæmia. When it is fatal, post-mortem examination usually reveals a large yellow liver showing intense fatty degeneration and necrosis of the hepatic cells. I am firmly of opinion that in these cases the fatty degeneration of the liver is not the result of the acidosis at all. The true explanation is to be found in the presence of some underlying toxic cause, such as infected tonsils or adenoids, intestinal toxæmia or grave errors in diet, whereby the liver degeneration is set up. The resulting impairment of liver function gives rise to prolonged vomiting and consequent lack of nutrition, which is quite an adequate explanation of the acidosis and ketonuria

FIG. 9.



Three cases of malignant malaria with jaundice. The first was fatal.

FIG. 10.



Three cases of malaria and influenza. In the third chart B = consolidation at right apex (tuberculous).

Acholuric Jaundice.—This condition is no doubt due to some auto-intoxication, probably one of the inborn errors of metabolism so admirably described by Sir Archibald Garrod. The jaundice in this condition is the perfect example of hæmolytic jaundice, and the van den Bergh reaction is typically indirect. Anoxæmia plays a part in its causation; in other words, the greater the anæmia the more marked will be the jaundice.

A review of the above types of toxic jaundice shows how varied may be their causes. Frequently in clinical practice a combination of the causes exists, as, for example:—

CASE 35.—A man, aged 45, gave a history of syphilis, and the Wassermann reaction was plus. Between April 4th, 1920, and June, 1922, he received 12 injections of 0·6 g. salvarsan. On Jan. 1st, 1928, he was given 0·3 g. and on Jan. 14th and 28th, Feb. 11th and March 9th, 0·6 g. On Feb. 15th 12 teeth were removed under chloroform anæsthesia, the operation lasting nearly two hours. On March 9th, in the evening after the last injection of salvarsan, the temperature rose to 105° and some vomiting occurred. On March 10th he went to business, fainted three times, was sick once, and had his bowels opened four times. On March 11th he was sick three times and jaundice developed. On March 12th the jaundice was deeper and the temperature was 99·5°. The urine contained a trace of albumin and a trace of acetone. Herpes developed on the right upper lip. On March 13th he was sick twice and had bleeding from the nose and gums. On March 15th stupor, delirium, twitchings, and coma developed, and signs of consolidation of the left lower lobe was marked. He died on March 17th, 1928.

Post-mortem examination showed degenerative changes in the liver cells and a terminal pneumonia of the left lower lobe of the lung.

The ætiological factors in the causation of the toxic jaundice were the salvarsan injections, the streptococcal toxæmia from the dental extractions and the chloroform given as the anæsthetic.

The Control of Poisons.

The consideration of the great variety of drugs in common use which may act as liver poisons and produce dangerous toxic jaundice shows how necessary it is that these drugs should be submitted to careful toxicological and therapeutic tests on the human subjects as well as on animals before they are placed on the market. The medical profession should be fully informed, not only of the therapeutic properties for good of new drugs, but also of the dangers which may arise from idiosyncrasy or overdosage. It cannot be said that this is the case at the present time. The existing system of scheduling of poisons is quite inadequate to keep pace with the rapid developments of the chemical manufacturing industries, which are daily launching new and imperfectly tried complex organic drugs on the market in this country.

As already pointed out, the quinophan group is not even on the Poisons Schedule, and can be sold by any unqualified person and purchased at will by the public without any medical intervention or advice. The system of the control and sale of drugs possessing powerful toxic properties is at present most imperfect and unsatisfactory. The people of this country are exposed to very great danger, for they can have little or no knowledge of the risks associated with new drugs which are advertised as possessing wonderful curative properties and of the toxic effects of which no mention is made.

The Pharmacy and Poisons Bill at present before Parliament proposes to place the control and sale of poisons under the supervision of an advisory committee called the Poisons Board, on which the medical profession will have a representation, which it is hoped will be adequate. This committee, or Poisons Board, will advise the Home Secretary on the steps to be taken whereby there shall be adequate control of the sale of drugs which may possess poisonous properties, and by this means the public should receive that adequate protection which ought to be afforded to it by the Government.

LATENT MAXILLARY SINUSITIS.

BY RALSTON PATERSON, *M.C.*, M.D., F.R.C.S. EDIN.

(From the Department of Radiology, Lockwood Clinic, Toronto.)

INFECTION in the accessory sinuses occurs more frequently than is realised. It is especially common in the maxillary antrum, owing to its lack of dependent drainage. The "common cold" is by far the most frequent cause, although occasionally infection develops after influenza, tonsillitis, or even trauma.

The acute infections are ordinarily very obvious processes, and tend to spontaneous recovery. They are really little more than part of the cold with which they appear. Chronic infection is a much more troublesome problem from both the diagnostic and the therapeutic point of view. It is found in three forms—as a frankly purulent sinus, as a sinus with chronically infected hyperplastic membrane, or as a sinus showing polypoidal degeneration of the membrane.

Both acute and chronic infections have a peculiar tendency to the production of secondary complications, the evidences of which dominate the clinical picture while the symptoms referable to the primary focus in the antrum are either absent or surprisingly slight. This condition I have called latent sinusitis. In its recognition a radiological examination is of especial value. Such cases, if examined, may or may not show intranasal indications of the sinus trouble.

It is difficult to estimate the incidence of such silent lesions. The cases reported are the noteworthy cases from a group of 425 in which the sinuses were X rayed during a routine clinical examination. Of these, 100 were found to show clouding of one or both maxillary sinuses. In 46 of these 100 cases the maxillary antrum was punctured and washed out. In 30 pus was obtained. Of the 30, 6 have been classed as absolute cases of latent sinusitis in so far as the primary sinus lesion was totally unsuspected before radiography, while the symptomatology was that of a secondary complication. In the cases quoted these complications included asthma, severe headache suggesting a migraine, exophthalmos, sudden blindness, possible "tic douloureux," and a painless swelling of the glabella.

From these figures it would seem, therefore, that X ray examination of cases in which any suspicion whatever can be directed towards the nose is worth while. Where there is radiographic evidence of clouding of the antrum, diagnostic puncture seems sufficiently justified and, except in the presence of an acute infection, is harmless. In a similar study of 300 cases, Johnson[1] found that where X ray and clinical findings both indicate pus in the antrum, pus is found in 98 per cent. of cases; but that, where the X ray alone shows clouding and clinical substantiation is lacking, 17 per cent. of cases show pus on puncture. This last figure is very similar to my own finding of 13 per cent.

It will be noted that the positive finding of pus in the antrum on puncture is here taken as the only positive proof of antral infection. The condition of those cases in which washings were negative in spite of a positive X ray is left as an open question. Drea,[2] reporting an analysis of 694 sinus cases, describes the appearance produced by polypoidal or œdematous mucous membrane and finds that about 50 per cent. of cases which show clouding are of this nature, and do not contain pus. In his group 99 polypoidal cases were operated on, and the polypoidal condition was found in 95 per cent. I have not been able to obtain an operative check on such cases. Whether this condition acts as a toxic focus in a similar manner to a toxic empyema or not is questionable. Sluder,[3] in his book, finds that the similar condition in the sphenoid—hyperplastic sphenoiditis—certainly acts as a source of considerable trouble. It would probably be safe to say that, even in the absence of pus on diagnostic puncture, a sinus showing clouding in the X ray, associated with definite clinical evidence of lesions similar to those described in this article, should be considered as potential primary lesions and treated. Where pus is found, of course, treatment is often rapidly efficacious, and the general condition of the patient improves considerably.

The importance of the complications of unsuspected antral infection has been considered extensively in the literature; all kinds of conditions from colitis to melancholia have been reported. The subject, however, has practically always been reviewed in any one article from the point of view of one particular type of complication only. A study of this literature suggests that the types of complication can be divided into several very distinct groups. I have outlined the following groups as distinct, and present illustrative cases and a brief résumé of the literature on each.

1. *Orbital.*—Where the structures within the orbital cavity only become affected.

2. *Intracranial.*—With involvement of the central nervous system.

3. *Cranial.*—Where referred pain via the nerves of the face or head dominates the picture.
4. *Thoracic.*—In which the complicating lesion appears as a disease of either lungs or bronchi.
5. *Miscellaneous.*—Including a group which could be further subdivided but into which only the rarer cases fall.

Orbital Complications.

CASE 1.—A stenographer, aged 26, had suffered considerably from abdominal trouble of various sorts for several years, and her health was generally poor. A year before coming to the clinic she had developed a cold, associated with quite definite soreness about the face and head on one side; her face had never felt quite normal since. She also complained of a slight but constantly troublesome cough since that time.

In October, 1929, she came to the clinic on account of her abdominal trouble, and was undergoing a general examination. On Oct. 1st she developed an acute coryza, but this cleared up very rapidly. Ten days later, on Oct. 10th, she complained of loss of vision in the right eye. This had come on comparatively rapidly over three or four days. She was found to have bare perception of light in the right eye; there was also a slight defect in the left eye. She was given a complete ophthalmological examination and was reported as a "retrobulbar neuritis." The following day, however, she was sent for X ray examination of the sinuses and the right antrum was found densely clouded. The leucocyte count was 8500. Although there was no intranasal evidence of trouble, the sinus was washed out and found to be full of pus. For the next two or three weeks the sinus was washed out regularly until the washings were perfectly clear. The vision gradually improved and in the end returned completely to normal.

CASE 2.—A call-boy, aged 18, came to the clinic in March, 1929, complaining of failing vision and of increasing exophthalmos of one eye, of about eight months' duration. Eighteen months before he had suffered a severe blow on the outer border of the cheek-bone and had a "black eye" for two weeks and a hard lump for months. It is impossible to say whether this injury had any relation to the subsequent developments, but no other history suggesting an ætiology for sinus infection was elicited. He was perfectly well for one year after this blow. A year later he found by chance that he had poor vision in the right eye. At that time he had no proptosis. He had a tonsillectomy and several dental extractions done, but without relief. For the six months before he came to the clinic there had been a slowly increasing protrusion of the right eye without any pain. His only other complaint was of occasional nasal discharge and, more recently, of headache.

On examination the boy was found to have a marked exophthalmos and a proptosis of 1·4 mm. downwards and outwards. There was defect of vision on that side, and ophthalmoscopy revealed an œdema around the edge of the right disc with swelling of the disc to 1·5 D. Nystagmus could be elicited on both sides. There was no intranasal evidence of trouble; the leucocyte count was 10,500. A tentative diagnosis of retro-orbital tumour was made at first.

On radiological examination a generalised clouding of all the sinuses on the right side was found and a pansinusitis reported (Fig. 1). Antral puncture was done and pus found. Surgery was advised. The radical frontal operation from the exterior, ethmoidal exenteration, and a "radical antrum" were performed; the orbit was not opened. An extensive infection was found and wide drainage was established. After the operation the sinuses were washed out repeatedly and the eye slowly began to recede, but at the end of four months it had not returned to normal. Nine months after the operation the patient's mother wrote that he had greatly improved. In April, 1930, however, he returned for a re-examination. There was some recession of the eye, but there was still a very definite exophthalmos and some vision defect. The movements of the orbit were, however, quite free and the patient had become able to focus. The nasal condition was good. The patient said that after the first recession after operation the condition had remained entirely stationary.

A study of papers [3–7] on the secondary effects of sinus disease shows a very extensive bibliography dealing with orbital involvement. This is particularly so in cases of infection of the posterior sinus groups, but also occurs with antral infection. The bony walls of the sinuses separating them from the orbital cavity are extremely thin, and there is a common lymphatic drainage system. Luedde classifies the types of lesion found into two groups, "functional" and "pathological." In the first group he places those cases in which the orbital symptoms are probably reflex. These include photophobia, conjunctivitis, blepharospasm, iritis, excessive lacrimation, and so on. Thomson points out the frequency with which this type of lesion occurs and the extreme importance of early diagnosis. Midway between this group and the "pathological" group lie the cases of so-called "retro-orbital neuritis" produced in all probability by pressure on the optic nerve itself, but without any actual intra-orbital abscess. In these cases blindness occurs, but there are no visible changes in the retina. Case 1 is an excellent example of this condition. The girl's sight was almost certainly saved by the early diagnosis and prompt attention. The condition has been likened by Luedde to "a foot gone to sleep." The pressure probably occurs in the bony canal of the optic foramen, and may be caused by a mild lymphatic œdema.

The "pathological" group includes cases of a more serious type. These occur when the infection actually spreads to and involves the orbital contents. This may cause actual inflammatory involvement of the optic nerve or of any of the other orbital nerves, or it may result in a retro-orbital abscess. These conditions will show as loss of vision, exophthalmos, strabismus, or the like. Case 2 is a good example of the "pathological" orbital group of complications. In view of the incomplete resolution after operation, associated, nevertheless, with a total absence of further advance, the strong probability is that the condition was one of retro-orbital abscess. A more complete cure, but with a greater degree of risk, might have been achieved by opening into the orbit from the nasal exposure. The special interest of this case is the entirely latent and painless onset and course in the presence of such a wide infection.

Almost invariably in these cases perimetric charting discloses the presence of quite extensive scotomata, and the occurrence of these, without other obvious ocular lesion and without retinal changes, is more suggestive of nasal origin than of anything else. These conditions are highly important in so far as prompt diagnosis and clearing up of the primary focus will often save vision that will otherwise be lost, either through secondary optic atrophy or by extension of the process to the cavernous sinus. It has been said that the question of operation should be decided rather by the ophthalmologist than by the rhinologist. Davis makes the statement that treatment is even more urgent in this type of case than in acute mastoiditis.

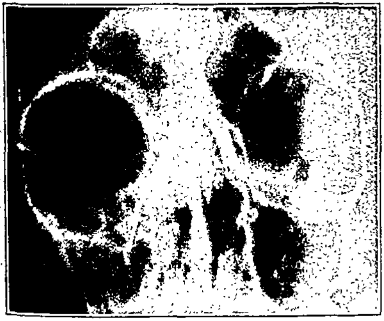
Intracranial or Cerebral Complications.

CASE 3.—A housewife, aged 41, had suffered from vague ill-health for about four years owing to a mild degree of cholecystitis. She was, however, otherwise normal. In May, 1929, two weeks before coming to the clinic, she developed a severe coryza, followed by a pain in the right side of the face. This only lasted a very short time, and the dull pain cleared up in a couple of days. A week afterwards she suddenly developed an acute fever with rigor at the onset, and an excruciating pain over the whole right face. Three days later she developed a feeling of extreme dizziness and a staggering gait and came to the clinic.

Examination showed localised supra-orbital tenderness, a right-sided nystagmus, the right pupil smaller than the left, and a staggering gait in some ways suggestive of a cerebellar lesion. The patient was suffering from acute spasms of pain. At first a tentative suggestion of "tic douloureux" was made. The nose was examined and was reported clinically negative. It was noted, however, that cocainisation of the nose relieved the headache to some extent. The leucocyte count was 6000. X ray examination of the skull and of the sinuses was done, and both antra were found to be completely obscured. The antra were washed out and large amounts of pus obtained. Antral windows were made for drainage. Relief was rapid, and a month later the patient was re-examined and seemed perfectly normal. Subsequently, in April, 1930, she was found to be suffering from recurrent but very mild headaches. The sinuses were X rayed again and were found to be perfectly clear.

Several interesting reports [8, 9] have been made on conditions which accurately simulate various types of mental disease but which appear to arise from and to be dependent on the presence of unsuspected antral infection. Such cases are very likely to be missed, and this is the more unfortunate in that cure results from effective treatment of the sinus condition. The ætiology is not understood but is presumably a local toxic effect. I have no very striking cases in my series, but Case 3 is illustrative of this process. Looper's report includes cases diagnosed as encephalitis, petit mal, narcolepsy, brain tumour, sudden coma, convulsions, and sudden delirium. In all of these complete resolution occurred after thorough treatment of diseased sinus conditions, which had been unsuspected until specifically looked for.

FIG. 1 (Case 2).



Generalised clouding of all the sinuses on the right side.

Cranial Complications.

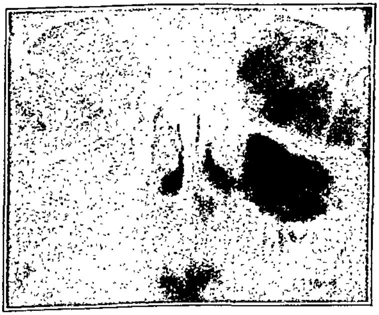
CASE 4.—The patient was a man of 44, normal to ordinary routine clinical examination. For 12 months he had been troubled with severe headaches practically every day. The pain occurred chiefly in the right eye, and over the right forehead and cheek. He stated that the pain was sufficiently severe to influence his mental activity; he felt himself to be duller than usual, and found it quite difficult to concentrate or to think. He gave a history of having had similar trouble three years before, which had been relieved by a dental extraction. He reported an occasional discharge from the right nostril, but the nose had been examined elsewhere and found normal. On clinical examination no causal lesion was found. On otolaryngological examination the nose was passed as normal; the tonsils were condemned as infected. The leucocyte count was 6300; the results of other laboratory examinations were insignificant. X ray examination showed marked clouding of the right antrum (Fig. 2). The antrum was punctured and washed, and frank pus was obtained. The patient was practically relieved of all his pain within a few days of the washing, and continued well as long as he was followed up.

The maxillary sinus is largely supplied by the second branch of the fifth cranial nerve through the spheno-palatine ganglion, and infective lesions within the sinus may originate referred pain in the other branches of, or the skin areas supplied by, the fifth nerve. This will result in headache or neuralgia, often of marked severity. The primary exciting factor is pressure, either the widely distributed pressure of a closed empyema or the more localised pressure produced by inflammatory exudate within the nerve sheaths supplying infected mucous membrane. The pain of the acute closed empyema is typical, and consists of an intense diurnal pain in the face and forehead, especially severe in the mornings, the face often being described as "feeling like bursting." Case 3, apart from its cerebral aspect, is a relatively typical example of an acute closed empyema of the antrum, the dominant symptom being pain. Case 4 is almost equally typical of a chronic closed empyema with tension. The mental dulling is of interest. It may have been secondary to the pain; it may also, however, have been evidence of intracranial toxic involvement, similar to the type described under group 3. The referred pain from the chronic lesions may, however, only affect a single branch of the trigeminal nerve, and show as infra-orbital or supra-orbital neuralgia, ear-ache, pain in the eye, frontal headache, or similar lesions. Sluder, in his book, describes such lesions under the title of spheno-palatine neurosis. It appears that such headaches may be excited as often from the antrum as from the sphenoids and ethmoids, as described by Sluder. In severe cases of lesions in this group, the pain may have all the characteristics of a "tic douloureux," the headaches those of severe migraine.[3, 10, 11]

Pulmonary Complications.

CASE 5.—A woman, aged 39, a housewife, gave a history of having suffered from "asthma" for three or four years, but before this she had been perfectly well. She gave no history of having had a severe cold at the time of onset of the disease, or any other suggestive history, but the onset had occurred a sufficient number of years before for details to have been easily forgotten. The asthma was constantly present, and had *not shown any seasonal variations.* About two years before she had had a tonsillectomy and a nasal operation (nature undiscovered), and had been improved for a period but not cured. The trouble as described by her was not of a paroxysmal nature but consisted of a chronic cough, productive of a moderate amount of mucopurulent expectoration, and a constantly "wheezing" type of respiration.

FIG. 2 (Case 4).



Clouding of the right maxillary antrum.

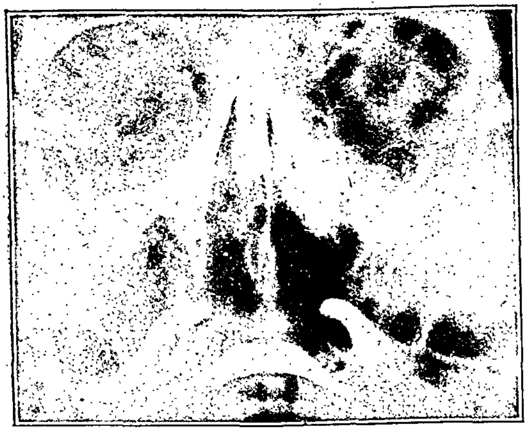
Otherwise she appeared clinically well, and nothing else was found on routine clinical examination. The white cell count was 8700. As a matter of routine, sinus radiograms were taken; these showed a markedly cloudy left antrum. The antrum was punctured and pus found. The antrum was washed out on four subsequent occasions, pus being obtained every time, but in very small quantity at the last examination. Following this course of antral lavage, the pulmonary condition became rapidly and spectacularly improved.

CASE 6.—A farmer, aged 20, complained of trouble with his throat and the bringing up of large quantities of sputum. He had had his tonsils removed when he was 8 and 12 years old. He had had this trouble for eight years—i.e., from the time of the second tonsillectomy. He always felt as if the throat was filled up, and he was unable to lie on his back without a severe paroxysm of coughing. During the paroxysms he reported that he was in the habit of bringing up large quantities of frothy sputum. Such an attack occurred while the patient was being examined; several cupfuls of highly purulent green sputum were coughed up. After such a cleaning-out he remained free of trouble for several hours.

On examination a severe chronic pharyngitis with considerable hypertrophy of the pharyngeal mucous membrane was noted. Considerable post-nasal dropping was also observed. The chest was radiographed after lipiodol injection, and an extensive bronchiectasis of the minor saccular type was found in the left base. The leucocyte count was 10,000. The sinuses were also X rayed, and clouding was found to be present in both antra (Fig. 3). These were punctured and washed, and pus was found in both. Bilateral "radical antrum" operations were done, and a great deal of degenerated membrane was scraped out. The patient was also put on conservative treatment for his bronchiectasis.

In many ways the most interesting of the secondary complications of sinus infections are those occurring in the respiratory system.[12–16] That there is a sound physiological basis for this has been demonstrated. On the one hand there is a very close inter-connexion of the lymphatic systems of the nose, the nasopharynx, and the thorax. On the other hand, it has been shown that foreign material or secretions from the nose and nasopharynx do find their way, often in sleep, into the bronchial tree. Mullin showed how Indian ink could be injected into the nasal lymphatics or into the sinuses and, later, particles discovered in the ultimate lymphatics of the bronchial tree. They also showed very similar results after the injection of tubercle bacilli. Quinn and Meyer, on the other hand, demonstrated that lipiodol left in the nose before going to sleep or dropped in during sleep passed into the bronchial tree in five out of 11 cases. It is thus easy to see how infection will carry from the sinuses deep into the lungs.

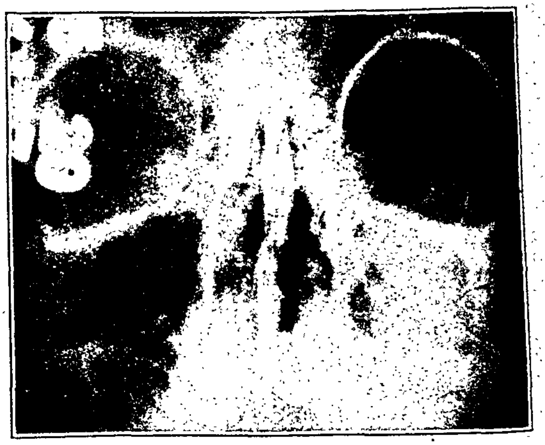
FIG. 3 (Case 6).



Clouding of both antra.

This relationship has also been shown statistically in studies of the ætiology of pulmonary disease both in the Army and in civil life. This fact has never been pointed out in the text-books—indeed, it was only first noted in 1916 by Rist and Sargent. Excluding tuberculosis or other specific pulmonary infections, a large percentage of pulmonary infections have a primary basis in a sinus lesion. So much is this the case that it has been said that investigation of the nasopharynx and of the nose should be a routine part of every chest examination. It has been found, too, that polypoidal conditions of the sinus membranes are as pathogenic in this respect as frankly purulent lesions. For this reason X ray examination is of particular value in this type of case. Kern and Schenck studied the sinuses in 200 cases of asthma both by X ray and clinical methods; they found a high incidence of sinus disease, and felt that, although both methods of examination were liable to considerable error, the X ray was of the two the more accurate. They also found that antral lavage is not an absolute criterion and that there are many chronically infected sinuses which do not show pus on washing. Brown has pointed out the frequency and importance of this type of thoracic complication in children.

FIG. 4 (Case 7).



Clouding of the left maxillary antrum.

The most common type of pulmonary infection is a chronic bronchitis productive of sputum and associated with a chronic cough. It is also found as true bronchiectasis, or passing under the diagnosis of "asthma." Case 5 is remarkably typical of reported cases. There was probably no extensive pathological basis within the bronchial tree, and the relief was rapid. If neglected, however, this type of case ultimately goes on to a definite bronchiectasis difficult to handle, such as is seen in Case 6.

In these cases the sinus lesion itself is practically always latent and painless, and very likely to pass unnoticed unless looked for. In one respect this group of lesions differs from those in the previous groups in that once they have become chronic, cure of the sinus lesion is not necessarily followed by resolution of the secondary lesion, although some amelioration of symptoms may occur. The lung lesion has to be treated independently. On the other hand, however, as long as the primary sinus focus remains present, no amount of treatment will relieve the thoracic complications for more than transient periods. For the same reason, prophylaxis is of the greatest value.

Miscellaneous.

CASE 7.—The patient was a young man, aged 22, apparently in perfect health. He came to the clinic on account of a peculiar painless swelling at the root of the nose over the glabella. This swelling was about 2 to 3 cm. in diameter, and raised about 1 cm.; it did not have the characteristics of an inflammatory swelling, was not tender, and was rather paler in colour than the surrounding skin. It felt doughy in consistency, rather like the œdema of a "white leg." The patient had had a "cold" some six to seven weeks before. On examination the interior of the nose was entirely normal; tumour and frontal bone periostitis were both considered as possible diagnoses. X ray examination of the skull suggested the presence of sinus clouding, and sinus rays showed definite clouding of the left maxillary antrum (Fig. 4). *The antrum was washed out and considerable pus obtained.* The sinus was washed periodically for the ensuing month. The swelling rapidly disappeared, and to date—one year later—has never recurred. It was presumably due to some peculiar form of local lymphatic obstruction.

While the majority of the lesions fall into the above groups as a natural result of the anatomy or physiology of the parts, yet there is also a small group of lesions which are difficult to classify. As a chronic infective focus an old-standing sinus lesion is always a possible cause for those diseases known to depend on the presence of toxic foci—the arthritides particularly. The sinuses should be as closely studied as teeth and tonsils in any cases where it is essential to eliminate "foci." Mithoefer[17] describes one interesting case of chronic colitis in which the disease disappeared almost immediately after effective treatment of a diseased sinus, the trouble presumably being due to and kept up by the constantly swallowed nasal discharge. Again, nephritis, especially in children, has been found to depend upon the presence of infected sinuses, and to fail to respond to treatment until the sinus had been attended to.

These conditions are illustrative of the possibilities rather than of special groups, and belong really to the interesting or curious findings of internal medicine. Case 7 is an illustration of just such an unexpected and anomalous finding. The types of complication described under the other groups are by contrast far from rare and far from anomalous, and their importance in the realm of internal medicine is still insufficiently realised.[18]

Summary and Conclusions.

Radiological examination of the accessory nasal sinuses often serves to draw attention to cases of antral infection. It may also disclose cases of latent empyema of the antrum, not otherwise discoverable. These cases are those in which the lesions complained of are secondary complications of an unsuspected sinus lesion. Such complications fall into five main groups. The orbital group includes an extensive series of reported cases of defects of vision and orbital complications of serious moment. The cranial group includes those producing headaches, facial pain, or neuralgia of various types. The cerebral group is an interesting group in which disease simulating mental disease is found to be entirely due to sinus infection. The thoracic group has been frequently described recently, and consists of those cases of non-specific pulmonary infection called chronic bronchitis, bronchiectasis, or asthma which are secondary to unsuspected sinus lesions. In addition there is a miscellaneous group in which distant lesions are unexpectedly found to depend on the presence of trouble within the sinuses. Illustrative cases are quoted.

THE MEINICKE CLARIFICATION REACTION FOR SYPHILIS

IN MENTAL HOSPITAL PRACTICE.

BY W. OGDEN, M.R.C.S. ENG., D.P.M.,

LATE MEDICAL OFFICER IN CHARGE OF INVESTIGATIONS ON GENERAL PARALYSIS, MAUDSLEY HOSPITAL;

AND

F. PARTNER.

(*From the Central Pathological Laboratory of the London County Mental Hospitals.*)

THIS paper records the results of parallel Wassermann and Meinicke tests made on 1000 sera forwarded to the Central Pathological Laboratory for routine examination.

Although the Wassermann reaction (W.R.) in the hands of the expert can be relied upon to give consistent and accurate results, it is generally accepted that wherever possible a parallel flocculation test should be made. In well-defined cases of syphilis there is fair agreement between most flocculation tests and the Wassermann reaction, but in treated cases this agreement does not occur, and the relative significance of the differing reactions will be discussed.

Michaelis,[1] in 1907, was the first to observe that precipitation occurred when a syphilitic serum was treated with organ extracts, and since that time numerous flocculation tests depending on this phenomenon have been described—e.g., Kahn, Sachs-Georgi, Sigma, Vernes, and Meinicke. Most of these have been reviewed in the League of Nations Report[2] on the sero-diagnosis of syphilis. The differences in technique depend mainly on the manner in which the organ extract is prepared, and the method by which the resulting flocculation, precipitation, and clarification is observed.

The Meinicke clarification reaction[3, 4] follows the Meinicke turbidity reaction; the organ extract is made from ox heart muscle, balsam of tolu is added to it, and the system is adjusted with alkali of varying strength till the isoelectric point of the colloidal suspension is approached, with the result that a positive reaction presents a clear-cut precipitation of the colloidal elements and clarification of the system.

The test can be set up in two forms:—

(*a*) The *macro-reaction*, a procedure which requires 0·7 c.cm. of serum and takes 16 to 20 hours to obtain a complete and quantitative reading; and

(*b*) The *micro-reaction*, which can be utilised where only small amounts of serum are available, as in pædiatric practice, in certain cases in mental hospitals, or where a rapid test is required. The reaction enables a result to be obtained within one hour.

It is claimed that hæmolytic, icteric, and cloudy

sera are all adaptable to the reaction, and further that a falsely positive result can never be produced by the admixture of blood or other contaminations with the sera.

Material and Method of Investigation.

The results reported here are taken from sera sent to the Central Pathological Laboratory of the London County Mental Hospitals for the routine W.R. test, and include a large number from cases of general paralysis both before and after treatment. The W.R. tests were made by the method adapted for mental hospital practice which has been used in this laboratory since 1910, and which is now accepted by the Royal Medico-Psychological Association as the standard method.[5]

The technique of the clarification test, as described by Meinicke,[3, 4] has been strictly followed, and the specially prepared and standardised "antigen" obtained from Meinicke's Serological Institute, Westphalia, has been used throughout the investigation; a four-tube test has been made on each specimen wherever the amount of serum permitted, failing that, in a few cases only the second and fourth tubes were used.

Some question had been raised as to the occurrence of non-specific reactions in cases of active pulmonary tuberculosis when tested by the older Meinicke turbidity reaction.[6] It was thought advisable, therefore, to examine the sera from such cases by the clarification reaction, and these results have been added.

On each specimen the W.R. and both Meinicke clarification tests were performed, and in the discussion of the main results the reading of the Wassermann is compared with the Meinicke macro-reaction. The results were read quite independently, and certain differences which occurred between the two Meinicke reactions will be discussed later.

In cases where the readings between the W.R. and Meinicke reaction differed inquiries were made into the histories of the patients to ascertain whether (1) there was any history of syphilitic infection, (2) there was any history of treatment for syphilis, (3) there were any clinical signs which might point to syphilitic infection in the absence of history. As a further aid, in a few of these cases it was possible to examine the cerebro-spinal fluid of the patient by the W.R.

Results.

An analysis of the first 1000 cases performed in this manner gives the following results.

1. *W.R. and Meinicke macro-test both negative (787 cases).*—These formed the greatest proportion of the cases, and amongst them were 13 known treated cases whose sera had become negative to both reactions.

2. *W.R. and Meinicke macro-test both positive (179 cases).*—The number of treated cases in this group was 87, and by far the greater proportion of these were general paralytics who had been treated by pyrexial methods (malaria or sulfosin), followed by some organic arsenic compound.

3. *W.R. negative and Meinicke macro-test positive (25 cases).*—Since this is the first group in which a difference between the two tests occurs, it is necessary to discuss it in a little more detail. Included in this number were 13 cases who had been treated for a syphilitic infection, and in whom the Meinicke reaction at the time of examination persisted as a positive, whilst the W.R. was negative. In general, positive reactions to flocculation and allied tests tend to persist longer in the treated cases than do the positive reactions to the Wassermann.

Of the remaining 12 cases, the histories and clinical signs, if any, were investigated.

One patient was a tabetic clinically, and examination of the cerebro-spinal fluid by the W.R. proved to be positive.

Another case also had clinical signs of tabes. The pupils were unequal and reacted very sluggishly to light. The knee- and ankle-jerks were absent, and there was loss of sensation to pin-prick over the forearms and legs. This patient died of pneumonia before an examination of the cerebro-spinal fluid could be made. Two other patients were senile, and had weakly positive reactions to the W.R. on the cerebro-spinal fluid. One other patient was said to have a "punched out" scar on the penis, and to have commenced having fits at a late age. One female patient suffered from corneal ulceration. She had had one miscarriage and 15 children, five of whom had died soon after birth or in the first year of life. In each of the latter cases the reaction of the cerebro-spinal fluid proved negative to the W.R.

The last patient to show any clinical signs was a man aged 48. The pupils were small, equal but irregular, and did not react to light. The knee-jerks were sluggish and the ankle-jerks could not be elicited. Bilateral extensor responses were present. There was no evidence of sphincter trouble. There was no history of syphilitic infection, and the cerebro-spinal fluid was negative to the Wassermann test.

In the remaining five cases both history and abnormal clinical signs were negative.

4. *W.R. positive and Meinicke macro-test negative (9 cases).*—Of this number seven were general paralytics who had been recently treated by malarial therapy followed by organic arsenic compounds. It is in this type of case that the Meinicke reaction appears to fail at times. The two other cases were also general paralytics, but no recent history of antisyphilitic treatment was given.

COMPARATIVE INTENSITY OF WASSERMANN AND MEINICKE REACTIONS.

The Table shows the *comparative intensity* of the W.R. and Meinicke reaction. The W.R. findings are quantitatively expressed in units of complement adsorbed per c.cm. of serum,[5] and the Meinicke results expressed according to the notation of intensity given by Meinicke in the description of the method[3, 4]—i.e., complete clarification in all the four tubes of the test, or, in the fourth tube only, representing a strongly positive reaction and noted ++++, and weaker reactions according to the clarification occurring in the first three tubes, the weakest being noted as + when clarification only occurs in the first tube.

Group.	W.R.	Meinicke.	Cases.	Group.	W.R.	Meinicke.	Cases.
1	+30+	++++	91	4	+10	++++	5
		+++	17			+++	8
						++	1
2	+30	++++	15	5	+7·5	+++	1
		+++	11	6	+6+	+++	2
						++	2
3	+15+	++++	9	7	Neg.	++++	6
		+++	16			+++	15
		+	1			++	4

It will be noted that a strongly positive W.R. is generally associated with a Meinicke reaction of similar intensity ++++ (Group 1), and that with a less marked W.R. (Group 2) the proportion of +++ Meinicke reactions greatly increases. This is also apparent in Groups 3, 4, 5, and 6, but in the majority of cases comprising these groups the W.R. of lesser intensity results from treatment, and it is evident that the Meinicke test shows a slower response to the effect of treatment. The cases in Group 7 also illustrate this finding: of the 25 cases noted, in 13 a negative W.R. followed treatment of previously positively reacting cases, with the Meinicke reaction remaining definitely positive.

In a recent report on the Meinicke test on 384 sera, by Prentice,[7] it was stated that the macro-test could be simplified by using only the last tube containing diluted serum, and that the reading of the first three tubes is unreliable. The results recorded above in no way support this statement, and it would appear that to make the test with one tube only seriously prejudices its accuracy, and certainly allows of no quantitative reading. Reference to the above Table will show that if a single tube test were adopted, approximately 40 per cent. of positive reactions would be missed. Moreover, the results recorded indicate that readings of the first three tubes are reliable, and have definite significance and support Meinicke's classification of strong and weak reactions. If the complete macro-test is carried out at varying periods after antisyphilitic treatment, it is possible to demonstrate quite clearly the weakening of the reaction in patients who are responding to treatment, as illustrated by the following case:—

Date.		W.R.		Meinicke.
July 25th, 1930	..	+10	....	+ + + +
Sept. 1st, „	..	Negative.	....	+ + +
„ 29th, „	..	„	....	+ +

MEINICKE MACRO- AND MICRO-TESTS COMPARED.

The micro-test was also made on all specimens recorded above. There was agreement between the macro- and micro-reactions, except in 12 cases in which the micro-test was positive, whereas both macro- Meinicke and W.R. tests were negative, and four cases in which the micro-test was negative where the macro- Meinicke reaction and W.R. were positive.

The positive micro-reactions of the first group were certainly of the weakly reacting type, but in the absence of confirmatory tests could not be ignored. They probably represent the pseudo-positive reactions referred to by Bousfield.[8] There appears to be no explanation for these false reactions other than the technical limitations of any drop method.

In the second group the variations arise from the fact that the micro- is a one dilution test, and if other dilutions were employed these few reactions might be found to be positive.

Altogether there is a fair agreement between the micro- and macro-reactions, but the few discrepancies noted indicate that the micro- is not so reliable as the macro-test, and should only be employed for reasons of urgency, and then should be confirmed by a subsequent macro-test, or in cases where it is only possible to obtain a few drops of blood.

THE MEINICKE TEST AND PULMONARY TUBERCULOSIS.

Specimens of serum from 30 active cases of pulmonary tuberculosis were examined. In 28 of these both W.R. and Meinicke reaction were negative. In one case both the W.R. and the Meinicke tests were positive, and in the other the W.R. was negative and the Meinicke positive. The latter case falls into Group 3 in the comparison of the main results, and amongst those in which no history or clinical evidence of syphilis could be found. In spite of this one apparently anomalous reaction out of the 30 cases examined, there does not appear to be any reason for believing that non-specific reactions occur in pulmonary tuberculosis.

Discussion.

The figures quoted show that the Meinicke macro- and the Wassermann reactions agree in 96·6 per cent. of the cases examined. It must be stated, however, that the high percentage of agreement bears some relation to the large number of negative results included in the series. If the 213 cases are considered in which a positive W.R. or Meinicke reaction was obtained, the results agreed in 84 per cent. of these cases. Of the 34 cases in which disagreement occurred among the 25 giving a negative W.R. 20 cases certainly had a definite syphilitic history; 13 of this number had previously given positive W.R.'s, which had disappeared under the influence of treatment.

Summarising these findings it will be noted that the majority of the instances of negative W.R.'s, associated with positive Meinicke tests, arose in syphilitic cases in whom the W.R. had been rendered negative by therapy. In only five cases could no specific history be obtained. The nine cases in which a positive W.R. was associated with a negative Meinicke test were clinically cases of general paralysis.

The above figures demonstrate that the macro-Meinicke clarification reaction has many advantages to offer as a parallel test in serological diagnosis by reason of the simplicity of procedure and general reliability. Unlike most flocculation tests for syphilis the reaction is clear-cut, and the end-point easy of interpretation. Fluctuations of temperature are more liable to affect the reaction in the first three tubes of the test than in the fourth, and where the heating arrangements of the laboratory are not operating throughout the night, the temperature of the room in which the tubes are placed may fall well below the optimum for the reaction (20° C.). To obviate this we found it necessary to place the racks containing the tests in an incubator set at 20° C. Meinicke stresses the importance of the temperature, and a short experience during the colder months served to emphasise this important point.

The results recorded indicate that a positive Meinicke in the presence of a negative W.R. may have some clinical significance, or in any case the positive Meinicke may persist in a treated case after the W.R. has become negative. It is, however, possible for a few negative Meinicke reactions to occur in definite syphilitic cases giving positive W.R.

The macro-test has proved more reliable than the micro-test, for whilst a specific case is rarely returned as negative, even when using one dilution with the micro-technique, pseudo-positive results may occur. In the macro-test wherein four tubes are used and larger amounts of the reagents are employed, no difficulty arises in reading clearly and correctly the result of the reaction.

Summary.

1. An analysis is made of 1000 parallel Wassermann and Meinicke clarification tests on sera from patients in the London County Mental Hospitals. An agreement has been found in 96·6 per cent. of the total.
2. Of the 34 cases showing a disagreement in the results of the two tests, 25 were negative to the W.R. and positive to the Meinicke test, and 9 showed a positive W.R. with negative Meinicke results. Of the former group, 13 had been treated for syphilitic conditions, 7 gave histories or signs of syphilitic infection, and in the remaining 5 cases no syphilitic history or clinical signs could be elicited. The latter group of nine cases were all confirmed clinically as general paralytics.
3. Evidence is produced to show that the Meinicke reaction tends to persist longer with the sera of treated cases than does the W.R.
4. The micro-test shows a 95·1 percentage agreement with the macro-test, but whilst representing a

useful rapid test where only minute quantities of blood are obtainable, it has not the same degree of reliability as the macro-technique.

5. The Meinicke macro-test is a useful parallel test to the Wassermann, especially in view of its simplicity of manipulation, clarity of results, and comparative freedom from non-specific positive reactions.

6. It is important to carry out the test in four tubes according to Meinicke's original technique, and the statement of Prentice that it can be made a one-tube test cannot be supported.

In conclusion, we would thank Dr. F. L. Golla, director of the laboratory, and Dr. S. A. Mann for their encouragement and advice in the course of this investigation.

OCHRONOSIS.

REPORT OF A CASE WITH CARBOLURIA.

By J. L. Berry, M.B. Birm.,

LECTURER IN PHYSIOLOGY IN THE UNIVERSITY OF BIRMINGHAM;

AND

S. Peat, B.Sc., Ph.D.,

ASSISTANT LECTURER IN BIOCHEMISTRY IN THE UNIVERSITY.

This case was diagnosed clinically on the grounds laid down by Osler,[1] who was the first to recognise the condition during life in three cases associated with alcaptonuria.

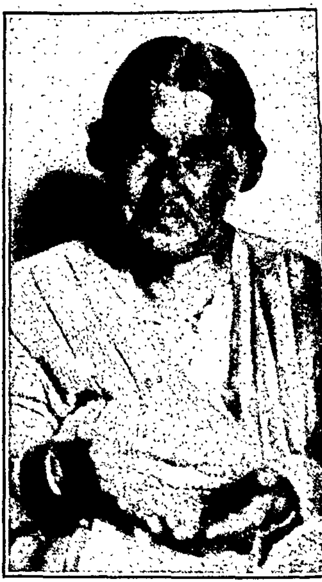
The patient, who was sensitive about her condition and reluctant to be the subject of investigation, was seen by one of us in 1927 when the diagnosis was made, but it was not until 1930 that she consented to help towards some of the results given in this paper.

Clinical History.

Condition in 1927.—Mrs. A., aged 59, complained of a progressive darkening of the skin of her face, which she thought had commenced about eight years before. The skin of her face was a uniform yellow-brown colour, except over the nasal cartilage, where it had a purple-blue tint. This gradually merged into the yellow-brown colour over the cheek in a butterfly-wing shaped area on each side. By standing well away from the patient, the observer gained from the purplish areas the impression of a butterfly's shadow over the face with the nasal cartilage forming the body; this, however, is not very well demonstrated in the photograph (Fig. 1). The sclerotics showed triangular symmetrical patches situated midway between the cornea and the canthus. The patches of pigment were deep to the conjunctiva, black in the centre and brown towards the margins, the four triangular areas being of approximately equal size and intensity of pigmentation. The base of each triangle was nearest to the corneo-sclerotic junction and the two sides ran nearly parallel with the margins of the lids. The ears presented the same peculiar purplish-blue pigmentation as that over the nasal cartilage, the concha being the most deeply stained. The aural cartilage was unduly rigid.

The hands showed a bluish tint on the skin over the thenar and hypothenar eminences, but there was no pigmentation of the nails. The flexor tendons at the wrist showed grey through the skin. The urine, when first seen, was yellow, contained a large amount of mucus and had a faint indefinable odour. The reaction was slightly acid to litmus and the specific gravity was 1016. Albumin was absent and Fehling's solution was not reduced but discoloured, Ferric chloride gave no blue colour. Microscopical examination of the deposit showed a few squamous epithelial cells and a few uric acid crystals. The urine on standing, darkened to a deep sepia tint within twelve hours but never became quite black. Decomposition did not occur on keeping for three days. On these grounds, the diagnosis of ochronosis was made.

FIG. 1.



Photograph showing pigmentation of face and hands.

Condition in 1930.—The patient was seen at various times during the years 1928, 1929, and 1930. On Jan. 23rd, 1930, she consented to physical examination. The examination revealed two large ulcers, one on each leg around and above the ankle. They completely encircled the leg and were about 10 cm. in width, the base of each consisting of unhealthy granulations. The skin at the edges was pigmented, but the pigmentation resembled that seen around old varicose ulcers rather than the characteristic tint of ochronosis. She now admitted the existence of the ulcers since she had had "white leg" in pregnancy forty years previously; they had been dressed with 5 per cent. carbolic acid lotion for a period of 35 years. This at once extended the investigation, since ochronosis has been recognised as being the outcome of alcaptonuria and also of the prolonged absorption of carbolic acid. With a view to ascertaining the true state of affairs, we proceeded to make a series of examinations on the urine—under certain difficulties, because the patient at that time was unwilling to be taken into hospital. On Oct. 13th, 1930, she was admitted to the General Hospital under Prof. W. H. Wynn, who gave us facilities for continuing our research and to whom we should like to express our thanks for his kindness. Daily samples of the urine were collected and dealt with in the manner set forth in the second part of the biochemical portion of this paper.

Condition in 1931.—The patient left hospital on Nov. 20th, 1930, the carbolic acid dressings being discontinued. No alteration in pigmentation of the skin, either in distribution or depth, was evident. The ulcers were healing with acriflavine dressings. She complained of backache and aching joints. Some arthritis was present in the back and knee-joints (? osteo-arthritis ochronotica). The urine was normal.

Chemical Investigation of the Urine.

PRE-HOSPITAL PERIOD.

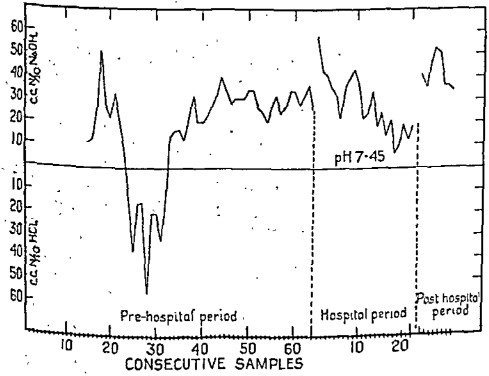
Between April and September, 1930, samples of the urine were obtained daily, but no data were available as to the time when it was passed or the diet taken. The urine was usually clear but contained for a period a large deposit of phosphates and mucus, coinciding with the period of alkalinity referred to later; the colour varied from the normal yellow to a smoky black. It usually darkened on keeping, this darkening process being greatly accelerated in alkaline solution. The darkening occurred at the surface and spread downwards, indicating an oxidative process. It was found by a series of experiments, using the Lovibond tintometer, that the darkening process was most rapid at pH 9·2.

Titratable acidity (on 90 samples) (Fig. 2).—The urine was usually acid, the titratable acidity varying from 10 c.cm. to 50 c.cm. N/10 NaOH per 100 c.cm. of urine, the mean value being 30 c.cm. N/10 NaOH per 100 c.cm. of urine. A *notable exception occurred with ten consecutive* samples which were on the alkaline side of the blood pH (7·45), varying from 14 c.cm. to 56 c.cm. N/10 HCl per 100 c.cm. of urine. This alkaline period was never repeated during the course of the investigation.

Sulphates (on 10 samples). The relative proportions of inorganic and ethereal sulphates varied only very slightly, the mean value for inorganic sulphate being 4 mg. SO_3 per 100 c.cm. urine, and for the ethereal sulphate 120·1 mg. per 100 c.cm.

Glycuronates (on 1 sample).—The glycuronic acid in one sample was estimated by Tollens' method[2] and found to be 77 mg. per 100 c.cm. of urine. This is three times the normal value as given by Tollens. The same sample of urine showed ethereal SO_3, 87·8 mg. and inorganic SO_3, 4·0 mg.; hence the ratio of glycuronolactone to ethereal SO_3 is 0·9 : 1. In normal urine, where the absolute amounts of glycuronolactone and of ethereal sulphate are very much smaller, Tollens[2] found the rates to be 2 : 1.

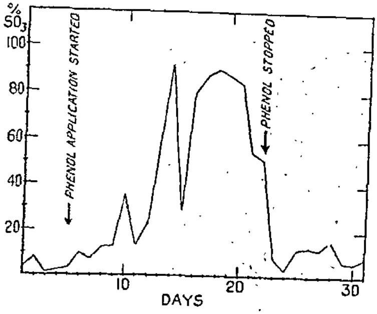
FIG. 2.



Titratable acidity curve. Consecutive daily samples, omitting week-end specimens.

Phenol.—The phenol was isolated as tribromophenol by distilling the urine with 5 per cent. hydrochloric acid (in later experiments with 5 per cent. sulphuric acid) and subsequently adding bromine to the distillate. The melting-point of the tribromophenol, once crystallised from 70 per cent. alcohol, was 87° C. No depression of the melting-point occurred in admixture with an *authentic specimen*. The amount of the bromo-compound obtained corresponded to 190 mg. of phenol per 100 c.cm. of urine. Probably the whole is present as sulphate and *glycuronate*.

FIG. 3.



Curve of urinary sulphate percentages. It should be noted that week-end specimens were not obtainable.

Homogentisic acid.—Repeated attempts to isolate homogentisic aid by the method of Garrod[3] were without success. The urine was heated to 90°C.; neutral lead acetate (5 g. per 100 c.cm.) was added and the solution was filtered hot. On cooling, a very small crystalline deposit (2·9 g. from 3500 c.cm. of urine) was obtained. The greater part of this proved to be lead chloride. The remainder after removal of the lead gave no colour with ferric chloride; did not reduce Fehling's solution; reduced ammoniacal silver very slightly, and did not progressively darken in potash solution—i.e., was not homogentisic acid.

Extraction of the Urine with Ether.—The urine was extracted in a "rocker" extractor with ether, and simultaneously the acidic extracts were absorbed from the ether either by N/10 NaOH or N/10 $Ba(OH)_2$, the former being the more satisfactory. The extraction was usually continued for four days. The alkaline solutions so obtained, which were usually black, were made acid to Congo paper with sulphuric acid and extracted with ether. The ether extract, after drying over calcium chloride, had the ether removed by distillation. The residue was then fractionated by vacuum distillation or vacuum sublimation or both.

(*a*) *Urine acidified with HCl.*—The ether extract distilled at 15 mm. yielded phenol, hydroquinone, and a little benzoic acid. Evidence for hydroquinone: the highest boiling fraction of the distillate (at 15 mm.) was crystalline. It crystallised from benzene in fine needles, M.P. 165–167°C. There was no depression in melting-point on admixture with an authentic specimen of hydroquinone (M.P. 168–169°). It immediately reduced ammoniacal silver nitrate and Fehling's solution and it turned dark in colour in alkaline solution. It gave no coloration with ferric chloride and on boiling with this reagent quinone was formed.

(*b*) *Urine acidified with sulphuric acid.*—The ether extract distilled and sublimed at 15 mm. gave phenol and much benzoic acid but no hydroquinone. A small quantity of substance, M.P. 120–174° C. (obviously impure), was also isolated. This unknown gave negative tests for hydroquinone. A black tar always remained after these distillations. The tar was soluble in sodium hydrate solution but not in sodium carbonate.

habit. The alimentary causes of chronic urticaria are of the nature of sensitisation, either specific (to a particular food) or non-specific sensitisation (to a great variety of foodstuffs, which variety is often not the same even from day to day). It may possibly be due to the absorption of toxic bodies or to the chemical changes in the blood which accompany constipation and consequent fermentation. The latter features, of course, are corrected by removing constipation. For the detection of sensitisation to specific foods, the method of skin tests offered great hope from the theoretical point of view, but has proved, in practice, of little value. Of more benefit is the keeping of a diary of the exact foodstuffs taken and the exact times of attacks of urticaria, when any correlation between the foodstuff and the urticaria is usually brought to light. If no such cause is found, it is not necessary or desirable to resort, with scant satisfaction, to some such vague but non-committal cause as focal sepsis, endocrine imbalance or biochemical derangement, in the absence of evidence, or to institute an interminable hunt for an elusive antigen.

It may be, and often is, true that some minor derangement of physical health or of mental equilibrium is permitting the persistence of a functional disorder which would disappear upon its correction, or it may be that the disorder of function has been allowed to persist for so long that now, in spite of good health, the habit continues. In the first instance, in the absence of a specific cause, we are called upon to restore the patient to normal health, and any disabilities discovered in the course of a reasonably careful clinical examination should be dealt with to this end. Examination of the urine should not be neglected; infected teeth should not be left in situ, in view of their possible secondary effects upon the general health; constipation should always be corrected; and habits of diet and meals should be put upon a normal basis. Undue nervous sensitiveness and particularly inadequate nervous rest, including sleep, should be inquired into, as should environmental factors, which may be exerting undesirable influences upon the physical or mental well-being. If such attention does not correct the disability, we should consider the possibility of bringing to an end the bad habit by sedative or shock measures. It should be borne in mind that urticaria is not uncommonly precipitated by an acute emotional upset or nervous shock and also that, being a highly sensitive vaso-motor nervous disorder, even if the acute precipitating cause has not been emotional, psychological factors will very readily step in as secondary provocative agents, once the reflex has been established. There is probably no group of skin affections or of medical disorders in which minor emotional disturbances play a greater part than in the production or persistence of chronic urticaria, and no case of chronic urticaria has received adequate consideration until this aspect has been reviewed.

Treatment.

The first measures instituted should obviously be eliminative, with a view to removing any possible poison emanating from the bowels and to correcting constipation. A great number of cases of chronic urticaria will clear as a result of these measures. In the second place, the general health and habits must be overhauled, any disorders found should be corrected and every effort should be made to see that the patient enjoys good and normal health. The dietary of the patient should next be reviewed, with a view to finding a possible cause in a specific foodstuff. If no specific cause is found, no useful purpose is served by dieting the patient stringently, on the contrary, full and normal diet should be taken. Too often one sees patients suffering from chronic urticaria in a state of starvation, and the restoration of normal diet does much to bring about recovery. Having conducted these preliminary investigations and corrections, the most important features in treatment are the internal measures prescribed. They fall into two groups: (1) measures of desensitisation and shock therapy; (2) measures directed towards the relief of nervous or emotional instability.

MEASURES OF DESENSITISATION.

If a specific protein is found to be the cause of the urticaria, the line of treatment is to exclude it from the dietary, or to endeavour to desensitise the patient by repeated ingestion or injection of small quantities of the offending substance. More commonly, no one specific foodstuff is found to be the cause. To deal with a general sensitisation to foodstuffs, the patient may be given a miniature meal one hour before the proper meal and of similar composition. This, however, is not a very practicable procedure and the same end is achieved by giving peptone, usually 0·5 to 1 g., one hour before meals. This is one of the most valuable measures in the treatment of chronic urticaria.

General desensitisation may be achieved in the same way by: (1) the intravenous injection of peptone once or twice daily, for a short period—5 c.cm. of a 5 per cent. solution usually being employed; or (2) the use of vaccines—e.g., T.A.B.; or (3) auto-hæmotherapy—the injection of 10–20 c.cm. of the patient's whole blood, taken from a vein at the elbow and immediately reinjected into the muscles of the buttock. Of all the measures demanding the use of the needle, auto-hæmotherapy is by far the simplest and often gives good results.

In this same class of treatment may be mentioned the administration of sodium hyposulphite, which may be given by mouth, or, more effectively, intravenously. This measure, which probably acts by its influence on the tissue cells, is more uncertain in its effect than the measures previously enumerated.

SEDATIVE MEASURES.

These provide the second line of attack upon chronic cases of urticaria. If, as is often the case, nervous influences are obviously playing the major part in the case, then this line of treatment will be adopted from the start. Its rationale presumes that hyper-excitability of the central nervous system is responsible for the exaggerated functional reactions, of which urticaria is the evidence. The most valuable measure here is probably potassium bromide, which is best given with sal volatile and nux vomica, as in the following prescription from the London Hospital Pharmacopœia: Pot. brom. grs. 10, sp. ammon. arom. ♏ 15, tinct. nucis. vom. ♏ 4, infus. gent. ad. oz. ½ t.d.s. p.c. Luminal in small doses—gr. ¼, or gr. ½—is exceedingly valuable. Valerian, phenacetin, and antipyrin are likewise of value, but are rarely as efficacious as bromides and luminal. It is quite hopeless to practise this line of treatment in a half-hearted fashion. If the diagnosis of the cause of a case of urticaria is correctly attributed to nervous influences the results of bromide or luminal therapy will probably be dramatic but will serve no good purpose at all if the treatment is stopped as soon as the symptoms are relieved. By means of sedatives one restores to normal a disturbance of function which has established a bad habit. It is also wise to take the patient gradually and not suddenly off sedatives used in this manner.

Another weapon of the same class, acting locally and not centrally, is superficial X ray therapy. A small application of X rays to the skin will restore normal function for a period and a few small applications, repeated at long intervals, will tend to restore normal function in much the same way as the administration of sedatives internally. Its great disadvantage in the treatment of urticaria lies in the fact that X ray administration to the whole of the surface of the body is a tedious procedure and is accompanied by a certain amount of temporary constitutional shock and depression.

TREATMENT OF CHRONIC PAPULAR URTICARIA OF CHILDREN.

This variety of urticaria, which is almost confined to children between the ages of one and three or four years, is probably dependent upon the two factors stressed—namely, a constitutional nervous sensitiveness and sensitisation of the skin to irritants gaining access by way of the alimentary canal.

Treatment should be directed, in the first place, towards correcting possible alimentary disorders and, if unsuccessful, should be combined with treatment of the nervous factor. In infants hyd. cum. cret., and in older children a mixture of rhubarb, magnesia, and bicarbonate of soda, will correct the disorder in the majority of cases. Most of those cases which resist such measures will be corrected by the simple addition of potassium bromide grs. 4 or grs. 5 t.d.s.

Local measures in the treatment of chronic urticaria of adults or children can afford no more than a measure of relief of the subjective symptoms and can do nothing towards curing the condition. Warm baths—often with the addition of bran—are comforting. Calamine lotion or liniment, with or without 1 per cent. carbolic acid, is usually sufficient by way of local application.

Urticaria should respond readily to treatment directed along correct lines. It does not serve any useful purpose to persist with a course of treatment in such chronic functional disorders unless favourable progress is apparent, for the cure of the disorder, if this eventually occurs, is more correctly attributed to time than to the treatment. In these circumstances the measures prescribed should be revised or withdrawn, for unnecessarily elaborate treatment sometimes encourages the persistence of such a disorder.

CLINICAL AND LABORATORY NOTES

ACUTE MONOCYTIC (HISTIOCYTIC) LEUKÆMIA.

By W. E. Cooke, M.D. Liverp., M.R.C.P. Lond.,
DIRECTOR OF PATHOLOGICAL DEPARTMENT, WIGAN INFIRMARY; CONSULTING PHYSICIAN AND CONSULTING PATHOLOGIST TO LEIGH INFIRMARY.

Reschad and Schilling-Torgau[1] described the first case of acute monocytic leukæmia in 1913. From that time to 1930 29 cases have been recorded, but Dameshek (1930)[2] reduced this number to 18, which included two cases described by himself. The reasons for his rejection of the other cases were that some were definitely myeloblastic leukæmia, others were of the acute myelocytic type, and some could not be differentiated from agranulocytosis. His rejection of these will be upheld by anyone reading the case reports.

THE PRESENT CASE.

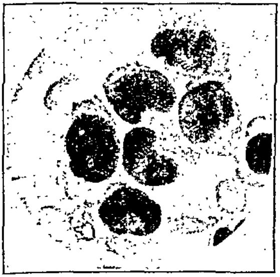
The patient was a boy, aged 19 years, a French polisher by trade, under the care of Dr. H. B. Lawrie, of Sabden, Lancashire. He was always healthy until August, 1930, when he was seen by Dr. Lawrie, but his family had noticed that he had looked pale for two months previously. When seen on Sept. 2nd he had had occasional rises of temperature—up to 100°F.—for the past three weeks, had become markedly paler, and had had some epistaxis and bleeding from the gums. The tonsils were large, and the gums swollen and granular. The spleen was enlarged, and extended 3 inches below the costal margin. The superficial glands were not enlarged, nor were there any petechial hæmorrhages. Blood examination on that date showed:—

Red cells	1,200,000	Polymorph	4 %
White cells ..	49,800	Lymphocytes ..	9 %
Hæmoglobin ..	22 %	Monocytes	87 %
Colour-index ..	0·9		

Thrombocytes very scanty. Monocytes all oxidase-negative.

The patient died on Sept. 12th. Autopsy was not allowed.

The "Type" Cell.—The normal monocyte of the blood stream was rarely seen in the films. The normal monocyte measures from 12 to 14 microns in diameter. The nucleus is large, varies in shape—rounded, indented, or horseshoe-shaped—and consists of a fine reticulum of chromatin. Nucleoli are not present. The cell is commonly oval, and sometimes presents cytoplasmic projections or pseudopodia. The cytoplasm stains a bluish-grey with Giemsa, and contains scattered azurophil granules. These cells are faintly oxidase-positive, the granules being very fine and scanty. The type cell of the present case differs from the normal monocyte in several important particulars. The cell is generally larger, measuring from 14 to 40 microns in the longest diameter. The nuclear structure appears even finer, and the shape of the nucleus shows more irregularity than in the monocyte. The nucleus is frequently folded upon itself and may show two or more folds. Nucleoli are not present. The cells take on innumerable shapes owing to the presence of pseudopods of different lengths and sizes (see Figure). The cytoplasm stains rather a lighter greyish-blue than that of the normal monocyte, and many of the cells contain very fine granules which are oxyphil and stain a reddish-pink with Giemsa, in contrast to the azure granules of the monocyte. The granules are often grouped round the nucleus. Furthermore, these cells are all definitely oxidase-negative. All stages from this cell to the normal monocyte may be traced in the films.



Six histiocytes described in the text. The folded nuclei and pseudopods are shown (× 1000). *Photomicrograph by W. E. Cooke and C. F. Hill.*

DISCUSSION.

The type cell in the above case was identical with the histiocyte (hæmohistioblast, clasmatocyte, or habit. The alimentary causes of chronic urticaria are of the nature of sensitisation, either specific (to a particular food) or non-specific sensitisation (to a great variety of foodstuffs, which variety is often not the same even from day to day). It may possibly be due to the absorption of toxic bodies or to the chemical changes in the blood which accompany constipation and consequent fermentation. The latter features, of course, are corrected by removing constipation. For the detection of sensitisation to specific foods, the method of skin tests offered great hope from the theoretical point of view, but has proved, in practice, of little value. Of more benefit is the keeping of a diary of the exact foodstuffs taken and the exact times of attacks of urticaria, when any correlation between the foodstuff and the urticaria is usually brought to light. If no such cause is found, it is not necessary or desirable to resort, with scant satisfaction, to some such vague but non-committal cause as focal sepsis, endocrine imbalance or biochemical derangement, in the absence of evidence, or to institute an interminable hunt for an elusive antigen.

More commonly, no one specific foodstuff is found to be the cause. To deal with a general sensitisation to foodstuffs, the patient may be given a miniature meal one hour before the proper meal and of similar composition. This, however, is not a very practicable procedure and the same end is achieved by giving peptone, usually 0·5 to 1 g., one hour before meals. This is one of the most valuable measures in the treatment of chronic urticaria.

General desensitisation may be achieved in the same way by: (1) the intravenous injection of peptone once or twice daily, for a short period—5 c.cm. of a 5 per cent. solution usually being employed; or (2) the use of vaccines—e.g., T.A.B.; or (3) auto-hæmotherapy—the injection of 10–20 c.cm. of the patient's whole blood, taken from a vein at the elbow and immediately reinjected into the muscles of the buttock. Of all the measures demanding the use of the needle, auto-hæmotherapy is by far the simplest and often gives good results.

In this same class of treatment may be mentioned the administration of sodium hyposulphite, which may be given by mouth, or, more effectively, intravenously. This measure, which probably acts by its influence on the tissue cells, is more uncertain in its effect than the measures previously enumerated.

SEDATIVE MEASURES.

These provide the second line of attack upon chronic cases of urticaria. If, as is often the case, nervous influences are obviously playing the major part in the case, then this line of treatment will be adopted from the start. Its rationale presumes that hyper-excitability of the central nervous system is responsible for the exaggerated functional reactions, of which urticaria is the evidence. The most valuable measure here is probably potassium bromide, which is best given with sal volatile and nux vomica, as in the following prescription from the London Hospital Pharmacopœia: Pot. brom. grs. 10, sp. ammon. arom. ♏ 15, tinct. nucis. vom. ♏ 4, infus. gent. ad. oz. ½ t.d.s. p.c. Luminal in small doses—gr. ¼, or gr. ½—is exceedingly valuable. Valerian, phenacetin, and antipyrin are likewise of value, but are rarely as efficacious as bromides and luminal. It is quite hopeless to practise this line of treatment in a half-hearted fashion. If the diagnosis of the cause of a case of urticaria is correctly attributed to nervous influences the results of bromide or luminal therapy will probably be dramatic but will serve no good purpose at all if the treatment is stopped as soon as the symptoms are relieved. By means of sedatives one restores to normal a disturb-works hard and is in perfect health, without symptoms of any kind.

The case is interesting because of (1) the gonococcal pyonephrosis; (2) the severity of the metastatic infection with slight and transient primary gonococcal lesion.

Gonococcal infections of the kidney are very rare. Although pyelitis is a fairly common complication of gonorrhœa, it is nearly always due to infection with other organisms of which the *Bacillus coli* is the commonest. In 1922 Simmons[1] found only 24 proven cases of gonococcal infection of the kidney in the literature, and of these only 15 were unmixed. In the other nine the associated organism was most often the *B. coli*. The onset varied from ten days to nine years after the original infection. Simmons described a case of his own in which a gonococcal pyonephrosis was found in a kidney which was ruptured by trauma. The original urethral infection was six months previous to the trauma, and there was evidence that the renal infection had been present for some time. He concluded that the infections were hæmatogenous, and that gonococci readily passed from the blood through the normal kidney without causing disease, but that if the kidney were already damaged, a gonococcal lesion might be produced. Support for this is given by Lavenant,[2] who in 1930 removed a kidney which was the seat of pyonephrosis. There was a mixed infection of staphylococci, *B. coli*, and gonococci; from the presence of a yellow abscess in the cortex, the route of infection was considered to be hæmatogenous. The condition had arisen after trauma, and had probably supervened on a hydronephrosis.

Similarly, le Fur[3] in 1904 found a gonococcal infection in a kidney previously the seat of closed aseptic hydronephrosis. There were no gonococci in the urine, nor was any cystitis present.

In the case reported here, although blood cultures were sterile, there is strong presumptive evidence of a gonococcal septicæmia, from the general condition of the patient and from the acute arthritis. That the kidney was previously damaged is probable in view of the rapid formation of an enormous pyonephrosis. It is unfortunate that no radiograms were taken at the onset, but the presence of large and dense calculi three months later argues their existence prior to the gonococcal infection. It is probable that a symptomless calculous hydronephrosis was complicated by the excretion of gonococci from the blood stream.

TOXIC EFFECTS OF INTRAVENOUS SALYRGAN.

By C. T. Andrews, M.D. Belf.,

RESIDENT MEDICAL OFFICER, HACKNEY HOSPITAL.

THE use of a complicated organic mercury compound in the treatment of heart failure dates from the introduction of novasurol as a diuretic by Saxl[1] in 1920. Some degree of mercurialism has been found to follow the use of this drug in 20 to 30 per cent. of cases, and novasurol as a diuretic has now been largely superseded by salyrgan, the use of which was first recorded by Bernheim[2] and Brunn[3] in 1924. Salyrgan is a white flocculent powder containing about 36 per cent. of mercury in combination with sodium-salicyl-allyl-amido-acetate. It is put up for injection in a 10 per cent. solution, and is given intramuscularly or intravenously in doses of ½ c.cm. to 2 c.cm. at about three-day intervals. It is usual to give ammonium chloride, in doses of grs. 20 to 30, thrice daily, at the same time.

The results so far recorded have been encouraging. Diuresis usually begins immediately after the first injection, and the total urinary secretion may rise to 100 oz. in the 24 hours. In a search of the literature I have not found any record of severe toxic symptoms following the use of this drug. Bedford[4] records 27 cases treated by salyrgan without toxic symptoms; Bernheim,[2] in 1000 injections, has not observed even slight toxic effects; other observers—Baker and O'Hare,[5] Brunn,[3] Herszky,[6] and Agnew[7]—have recorded similar results.

NOTES OF A CASE.

I have used the drug in nine cases of congestive heart disease. In eight of these a varying degree of diuresis was established. In one, toxic symptoms of such severity were produced that I have ventured to record the case.

A female patient, aged 22, was admitted to Hackney Hospital complaining of cough, shortness of breath, and swelling of the feet and legs of 12 months' duration. There was a history of rheumatic fever at seven. On examination she was found to be dyspnœic and slightly jaundiced. The heart-rate was 116, but the pulse was regular, and the blood pressure was 120/30. There was considerable cardiac enlargement, the apex-beat being in the sixth space in the anterior axillary line, and the right border 2 inches from the sternum. Double mitral disease and aortic reflux were found to be present. There were well-marked signs of pulmonary congestion. The liver was enlarged, the anterior edge being 3 inches below the costal margin. There was a moderate degree of ascites, well-marked œdema of feet and legs, and slight albuminuria.

Under digitalis therapy—ʒ iv. of the tincture in the first 24 hours, later reduced to ♏ xv. t.d.s.—the pulse-rate fell to 70 in three days, but after a week's further treatment with digitalis and saline diuretics, combined with restricted fluid and salt intake, the œdema had only slightly diminished.

Treatment with salyrgan was then begun. The technique used was that described by Bedford[4]; the dose was ½ c.cm. diluted to 10 c.cm. with sterile distilled water, and given into a vein at the bend of the elbow. The time taken for the injection was about four minutes. Before the full dose had been given the patient complained of headache. Fifteen minutes later she suddenly lost conciousness, and the upper limbs and face became involved in a clonic spasm of about 30 seconds' duration. The features became blanched during the seizure, the pulse became rapid and almost imperceptible, and the heart sounds during the attack were almost inaudible. The clonic spasm was followed by vomiting, which was repeated several times in the next hour.

In the 12 hours following the injection the patient had five similar seizures. Pallor was a marked feature of each; there was temporary loss of consciousness and each attack was followed by vomiting. No diuresis followed the injection; whereas the average daily output of urine for the four days preceding the injection was 33 oz., the average for the four days following was 24 oz. The blood-urea on the day following the seizures was 37 mg. per 100 c.cm. A urea-concentration test gave normal findings.

DISCUSSION.

I can state definitely that there is no possibility of an error having been made in the dilution of the salyrgan solution. The possibility of coincident uræmic manifestations is also definitely excluded by the blood-urea and the urea-concentration test. The marked tachycardia and pallor suggest a vaso-motor origin for the symptoms here described, and Jackson[8] has brought forward experimental evidence to show that the action of salyrgan extends to most, if not all, of the vascular structures of the body. We must assume that this patient possessed a marked degree of susceptibility to the drug, because the dose employed was much smaller than the average dose in general use. Possibly it would be advisable to test the susceptibility of the patient with a smaller dose than the ½ c.cm. generally employed. I now give three preliminary injections of ½, 1, and 2 c.cm. intramuscularly at three-day intervals, and then continue with 2 c.cm. intravenously if no reaction follows.

MEDICAL SOCIETIES

ASSOCIATION OF AMERICAN PHYSICIANS.

THE forty-sixth annual meeting of this association was held at Atlantic City on May 5th and 6th under the presidency of Dr. RUFUS COLE (New York). One of the discussions was devoted to diseases of the blood.

Monocytic Leukæmia.

Dr. P. W. CLOUGH (Baltimore) read a paper in which he said that monocytic leukæmia, although rare, had excited interest because its demonstration would support the independent status of the monocytes. He had found reports of 16 cases which conformed to the criteria, and he now brought forward an additional case.* They had clinically resembled acute leukæmia of other types, and had been characterised by a marked relative and absolute increase in the number of monocytes in the circulation. In his own case, as in most of the others, there were many immature cells ("monoblasts"). The cells showed the finely reticulated nuclear structure typical of monocytes, a greyish-blue cytoplasm, and reddish-lilac granules which did not take an oxidase stain. Relatively large numbers of the cells showed phagocytic activity in stained films. At autopsy there was a very widespread leukæmic infiltration of the tissues with reticulum cells that exactly resembled the monocytes in the blood. This was particularly marked in the connective tissue around the vessels. There were also changes in the endothelium of the vascular spaces of the spleen, which had been regarded by some as evidence of hyperplasia and desquamation of these cells and of their development into monocytes. In many of the collected cases, said Dr. Clough, there had been some associated myelocytic hyperplasia—a finding which had led some hæmatologists to regard monocytic leukæmia as merely a variant of myeloid leukæmia. It seemed more reasonable to accept it as a distinct system disease, in which, however, there was often some associated disturbance and perverted activity of other parts of the hæmopoietic system.

Dr. G. R. MINOT (Boston) said: "We had about 12 cases of monocytic anæmia, and about four of them showed very definite symptoms of acute arthritis after the leukæmia developed." He asked if Dr. Clough's case or others recorded showed any arthritic manifestations.—Dr. CLOUGH replied that he did not think anything of the kind was noted.

AGRANULOCYTOSIS.

Dr. G. M. PIERSOL and Dr. R. STEINFOLD (Philadelphia) said that a classification of granulopenias was proposed as follows:—(*a*) *primary:* (1) acute (Schultz), and (2) chronic or recurrent. (*b*) *secondary,* due to general and focal infections, chemical causes, irradiation, and blood diseases. The occurrence of benign types, particularly those due to focal infections, was exemplified by several case reports. The mechanism of granulopenia had been studied experimentally in rabbits, by the inoculation of various bacteria which had been from time to time found in conjunction with the condition. The effect of altered states of reactivity had been considered, based on their resemblance to those cases associated with focal infection. Hyperergy and the Schwartzman phenomenon particularly were studied.

Dr. A. E. TAUSSIG (St. Louis) said that the number of cases of agranulocytosis now reported justified a first attempt to estimate the value of the various methods of treatment. Three methods only were of importance—namely, intravenous injections of small doses of neoarsphenamine, blood transfusion, and irradiation of the long bones with the X ray. An analysis of 340 cases showed a total mortality of 79 per cent. For the purpose of evaluating therapeutic procedures the cases which proved fatal within 48 hours of beginning treatment were discarded. This left 80 patients treated by means of irradiation of the long bones, with a mortality of 53 per cent.; 49 patients treated by means of transfusion, with a mortality of 69 per cent.; 31 who received neoarsphenamine, with a mortality of 77 per cent.; while of 172 patients who received other methods of treatment, 75 per cent. died. It seemed then that only irradiation and transfusion promised even reasonably satisfactory results. It would probably be wise to use both methods in the treatment of a severe case, and doubtless the results would be better the earlier the methods were applied. During the past 12 months, said Dr. Taussig, seven cases of agranulocytosis had been seen at the Jewish Hospital of St. Louis. Of these, two were moribund when admitted, and died the same day; a third received only symptomatic treatment, and also died. The remaining four were given stimulating doses of X rays over the long bones. Of these, two recovered, responding rapidly to the treatment and were discharged clinically well. The other two also responded promptly and satisfactorily to X ray treatment, the blood picture becoming normal, the fever and angina subsiding. After an interval of well-being, however, both cases relapsed, and in this relapse were refractory to X rays. Both died in coma.

In reply to a question, Dr. Taussig said that the object of treatment was to get an effect on the bone-marrow. The maximal amount of marrow, with the minimal amount of tissue over it, was in the long bones.

---

* A further case reported by Dr. W. E. Cooke will be found on p. 129.—ED. L.

Hæmoglobin-production and the Liver.

Dr. G. H. WHIPPLE (Rochester, N.Y.) pointed out that hæmoglobin regeneration in experimental anæmia had received much attention during the last few years. The experiments of Robbins and Whipple were concerned with a simple anæmia due to withdrawal of blood.

This experimental anæmia in dogs was maintained at a given level—40–80 per cent. hæmoglobin or one-third of the normal hæmoglobin level. New hæmoglobin produced above this level was withdrawn and measured, thus keeping the anæmia level constant and evaluating the potency of any given diet for the production of hæmoglobin under these conditions. These dogs had been kept anæmic for years—in some cases seven years—and were in a state of perfect health and activity. The reaction to fixed diets was very constant, and repeated experiments in the early or late years of the anæmic period would show a similar hæmoglobin output. "With this base-line control for anæmic dogs," said Dr. Whipple, "we may record interesting differences in Eck fistula dogs, one continuously anæmic for six years." The Eck fistula dog was below the average normal for hæmoglobin production on various standard diet intakes. As was well known, when it was poisoned by chloroform, the liver was injured and the normal repair of this central necrosis might be very greatly delayed. Under certain conditions, therefore, the Eck fistula liver might approach a physiological insufficiency. Under favourable conditions, following chloroform poisoning of an Eck fistula dog, it had been observed that the output of hæmoglobin on standard diet intake might fall to a level about half that of the Eck fistula before the chloroform poisoning. In one case this condition was followed after eight months by a return of liver function to normal and a normal hæmoglobin output. This suggested that the liver takes an important part in hæmoglobin production. The liver perhaps helped in the grouping of amino-acids essential to the formation of parent pigment substances which were utilised by the bone-marrow to produce finished red cells. This observation was in harmony with the well-known fact that liver feeding enabled an animal or human to produce large amounts of new blood-cells. This helped to supply a logical explanation for success of liver diet in anæmia.

The Active Substance in Liver.

Dr. W. W. PALMER and Dr. R. WEST (New York) communicated a note in which "barium salts of acids derived from liver, highly active in pernicious anæmia," were described. From these, they said, a quinine salt had been isolated, and on hydrolysis, β-hydroxyglutamic acid and γ-hydroxyproline had been identified. More recently Dakin had isolated the quinine salt of a tribasic acid from liver, which contained the pyrrolidine ring, and had a higher melting-point and quinine content than those of acids previously reported. Injections of 700 mg. of this acid had given in two instances modest reticulocyte rises, up to 15 and 20 per cent., with red blood-cells at about one million. A crystalline substance had also been isolated from the regenerated barium salts, which was highly potent clinically.

Microcytic Anæmia in Middle-aged Women.

Dr. DOUGLAS VANDERHOOF (Richmond, Va.) reported five cases presenting a type of anæmia and certain clinical features suggesting a disease entity. The patients were all women, the youngest aged 37, and the oldest 46. The anæmia was chronic, having lasted from 11 years to 15 years in four cases, and at least two years in the other. There had been no remissions nor any symptoms or signs suggesting degeneration in the spinal cord. *Four of the* women showed the typical *tongue of atrophic* glossitis. Fractional gastric analysis showed achlorhydria in four cases, with no response after the hypodermic injection of 0·5 mg. histamine in three, while one patient showed a slight secretion of free hydrochloric acid after the histamine. In the fifth cases achlorhydria was strongly suspected, but the patient refused gastric analysis. All suffered from weakness, palpitation, and breathlessness, and four complained of digestive disturbances. Three listed diarrhœa of the morning type as a prominent symptom. All had menstrual irregularities with menorrhagia.

When these women first came under observation, the hæmoglobin ranged from 40 to 58 per cent. in four, with red cell counts from 3,200,000 to 3,900,000. In the fifth patient the hæmoglobin was 65 per cent. and the red count 4,200,000. All showed a low colour-index. The striking feature of the blood picture, however, was the small size of the red blood-cells. Their mean diameter was under seven microns in every case, ranging from 6·32 microns as a minimum, to 6·96 microns as a maximum. This blood picture, said Dr. Vanderhoof, might properly be classified as microcytic. It was of the hypochromic or chlorotic type, but the total red cell count tended to be lower than in true chlorosis, and the atrophic glossitis and gastric anacidity were distinguishing features in the cases reported. Treatment consisted of large doses of iron and adequate hydrochloric acid therapy. Instead of the iron an aqueous liver extract could be used with good results. The anæmia gradually recurred when treatment was omitted.

Dr. W. S. THAYER (Baltimore) pointed out that in severe chlorosis the blood count was usually reduced. In 1890–91 he had followed carefully 60 to 70 cases of chlorosis throughout their course. There was almost always considerable oligocythæmia, but the oligochromæmia was always relatively more marked. He thought that a normal red cell count with a very low hæmoglobin percentage was rare.

Iron in Anæmia.

Dr. G. R. MINOT and Dr. C. W. HEATH (Boston) gave a paper on the Response of the Reticulocytes to Iron, and Some Aspects of Iron Therapy. In pernicious anæmia without serious complications, treated with maximal amounts of liver or potent substitutes, the height of the reticulocyte rise, said Dr. Minot, was inversely proportional to the level of the red blood-cells and hæmoglobin before treatment. Similar, but less exact, relationships existed in anæmias responding to iron. Infections and other complications might hinder the action of iron, just as they hindered the action of potent material in pernicious anæmia. Distinct rises of reticulocytes occurred in response to iron with relatively high red blood-cell levels, at which in pernicious anæmia insignificant increases took place. With low hæmoglobin values the reticulocytes, in response to adequate treatment, increased much more in pernicious anæmia than in secondary anæmia. Both the hæmoglobin and red blood-cell level must be considered in evaluating the reticulocyte response to iron. For a given red blood-cell level the reticulocyte response to maximal doses of iron would be greater the lower the hæmoglobin, and the response for a given hæmoglobin level the lower the red cell count. Although in pernicious anæmia the distinctions were not so great, there was a tendency for the reticulocyte response at any given red blood-cell level or hæmoglobin level to be slightly greater in direct proportion to the colour-index. The exact type of case should also be considered in evaluating the reticulocyte response to iron. In cases with similar red blood-cell and hæmoglobin levels there was a tendency for those with achlorhydria to have reticulocyte responses to iron of less magnitude than cases with free hydrochloric acid in their gastric contents. There was, in general, a direct relationship between the height of the reticulocyte rise and increase of hæmoglobin; at least when before iron is given the hæmoglobin is less than 40 per cent.

REVIEWS AND NOTICES OF BOOKS

Modern Surgery.

Tenth edition. By John Chalmers Da Costa, M.D., LL.D., F.A.C.S. Assisted by Benjamin Lipschutz, M.D., F.A.C.S. London: W. B. Saunders Company. 1931. Pp. 1050. 45*s*.

This is the tenth edition of a work which has long established its worth. The great advantage of a text-book written by a single author resides in its uniformity of outlook. Although the assistance of Dr. Benjamin Lipschutz has been enlisted, the essential nature of Dr. Da Costa's book has been preserved. The two authors set themselves the task of true revision—that is, the inclusion of such of the new work as is worthy, the rejection of such of the old work as has proved faulty in conception and wanting in practice. They have avoided undue submission to fashion, while at the same time escaping from the trammels of ingrained habit and tradition. There is breadth of view and surgical judgment apparent in the teaching on almost any subject about which the reader may desire information. Modern ways of tackling old problems, such as Orr's method for osteomyelitis, or the Henderson operation for recurrent dislocation of the shoulder, are described and assessed, and the value of the descriptions is enhanced by the references to original sources of information. The practical nature of the work is exemplified by the discussion on injuries to tendons. Throughout the reader is encouraged to refer to recent work. This confidence in the judgment of the authors is likely to be consolidated by the candour and modesty of their remarks upon the operative treatment of exophthalmic goitre. This is a very good text-book of surgery, indeed a scholarly book, which could only have been written by men of culture, discernment, and experience.

Abdominal Pain.

By John Morley, Ch.M., F.R.C.S., Assistant Surgeon, Manchester Royal Infirmary; Surgeon, St. Mary's Hospitals, Manchester. Edinburgh: E. and S. Livingstone. 1931. Pp. 191. 10*s*. 6*d*.

In this book Mr. Morley attempts to give an explanation of the mechanism of distal and local pain in abdominal disease. His clinical observations have convinced him that Mackenzie's views are incorrect—i.e., that viscero-motor and viscero-cutaneous reflexes do not exist. He postulates a peritoneo-cutaneous radiation of pain and a peritoneo-motor reflex. There are numerous interesting clinical observations brought forward to support the hypothesis. Though the book is a very stimulating one to read it does not convince beyond doubt. There is definite experimental evidence of a viscero-motor reflex, and it is a little difficult to believe that in renal colic there is no such thing as a viscero-cutaneous radiation of pain. The whole subject is excessively difficult to elucidate, and we agree with the author that much investigation must necessarily be clinical in nature. The careful observations recorded here are a definite contribution to knowledge and provide an incentive to further study which will no doubt help to clear up this obscure branch of human physiology.

Clinical Examination and Surgical Diagnosis.

By Felix Lejars, Professeur de Clinique Chirurgicale à la Faculté de Médecine de Paris; Chirurgien de l'Hôpital St. Antoine. Translated by Helen C. Scott, M.R.C.S., L.R.C.P. London: Jonathan Cape. 1931. Pp. 872. 50*s*.

Chirurgische Diagnostik.

By A. J. Cemak. Vienna: J. F. Lehmanns. 1931. R.M.18.

Prof. Lejars's book in its French form is familiar to many surgeons. It has been most ably translated by Dr. Helen Scott, who has succeeded in conveying the meaning of the author and retaining the charm of his style. There is no other book quite like it in English. The student is taught the technical details of how to examine each region of the body as clearly as it is possible to teach him by the written word with the aid of pictures. The meaning of signs elicited is then discussed and the bearing of such findings upon the diagnosis. The whole plan of the book has been carried out extremely well, and no student can fail to learn much from reading it. His interest will be retained throughout. Though the illustrations, which reach the astonishing number of nearly 1100, serve their purpose in demonstrating the points that the author wishes to make, they have suffered in the reproduction, perhaps because the paper is not quite suitable or perhaps because so many impressions have already been taken from the original blocks.

"Chirurgische Diagnostik" is a new enlarged edition of a well-known atlas of surgical diagnosis. The chief change in it, beyond an increased number of illustrations, is the addition of many more tables of diagnosis, which are most useful for reference, though rather unsuitable for elementary students who are learning their work for the first time. Some coloured pictures appear in this edition which were absent from the former. The reproductions leave nothing to be desired in quality and there are 568 of them. Good as former editions were, this is better; it is more complete.

Calcium Metabolism and Calcium Therapy.

By Abraham Cantarow, M.D., Assistant Demonstrator of Medicine in the Jefferson Medical College, Philadelphia. Philadelphia: Lea and Febiger. 1931. Pp. 215. $3.75.

Lord Kelvin used to say that it is only when we learn to measure a thing that we really begin to know anything about it. Since it became possible to estimate accurately the blood calcium, we have begun to learn something of the mechanism of the calcium exchange in the body. Dr. Cantarow points out how progress in the knowledge of this subject has been made by investigators in physiology, chemistry, pharmacology, medicine, and experimental pathology. He makes it quite clear, however, that in spite of our increasing recognition of the importance of calcium in the economy of animals and plants, our knowledge of the physico-chemical regulations of inorganic salt metabolism is somewhat crude. The complexity of the mechanism of regulation of calcium metabolism renders the bulk of the literature on this subject incomprehensible to clinicians who have not been specially concerned with the subject.

Dr. Cantarow divides his book into three parts: normal calcium metabolism, abnormal calcium metabolism, and calcium therapy. In Part I. he deals with calcium absorption and excretion and the blood calcium. The factors involved in the maintenance of the normal serum calcium level are discussed in a separate chapter. He goes with considerable detail into the functions of calcium in the body. In this section he includes bone formation, membrane permeability, cardiac action, coagulation of blood and milk, nerve and muscle excitability, capillary permeability, acid base equilibrium, and water balance. In Part II. disorders of calcium metabolism are set out in detail. Rickets being too big a subject to discuss fully, Dr. Cantarow concerns himself very little with morbid anatomy, but he recognises that biochemical investigations have served to emphasise the truth of the original claims of Pommer and Schmorl as to the essential identity of rickets and osteomalacia. Hypoparathyroidism is discussed, and hyperparathyroidism is described in detail, though no space has been found for outlining the morbid anatomy and histology of generalised osteitis fibrosa. In a chapter on the disturbances of the level of the blood calcium and calcium partition the author describes the conditions under which hypocalcæmia is found, and some of the conditions associated with hypercalcæmia. Gastric tetany, phosphate tetany, and the tetany associated with hyperpnœa and with excessive dosage of bicarbonate are clearly set out. In Part III. the use of calcium salts by oral, subcutaneous, intramuscular, and intravenous administration is related in detail. The effects of the parathyroid hormone, of vitamin D, and of ammonium chloride on calcium metabolism are all described. Then follow a chapter on the treatment of tetany, and a last chapter on non-specific calcium therapy. The treatment of rickets and osteomalacia is not considered.

The book is well and concisely written, and almost entirely free from misprints. An excellent bibliography is appended. The author has succeeded in placing in an accurate and readily available form the whole of the useful knowledge on a new and important subject.

The Slum: Its Story and Solution.

By Harry Barnes, F.R.I.B.A., F.S.I. London: P. S. King and Son, Limited. 1931. Pp. 398. 18s.

Major Barnes knows a great deal about housing, both historically and as a contemporary problem. In this book he traces the three main channels along which legislative effort has flowed: the building Acts, deriving from Lord Shaftesbury; the reconditioning Acts, of which Torrens was the pioneer; and the Acts for slum clearance, whose first parent was Sir Richard Cross. Major Barnes gives impressionistic sketches of these and other champions of housing reform. He also supplies some interesting examples of time-lag; he tells us, for instance, that Joseph Chamberlain suggested in 1885 the "willing seller and willing buyer" formula for compulsory purchase, which was at last incorporated in the Acquisition of Land Act of 1919. With regard to present-day housing efforts, Major Barnes argues that we are not likely to make satisfactory progress so long as initiative is left to a large number of local authorities. He wants to see housing commissioners working on a large scale all over the country. It is a plea worth careful consideration. Major Barnes also thinks that in London and other great cities there is no practicable alternative to rehousing in high buildings. Not sufficient is said about the reconditioning of houses, of which a great deal more might be done with advantage at the present time. And the author's treatment of the pig-and-sty question is quite inadequate. Major Barnes does, however, advocate management by skilled women workers on the Octavia Hill system. The book would have been better if the author had cut out a number of rhetorical and jocose passages.

Radiologische Praktika.

Vol. XVII. *Röntgendiagnostik der Gallenblase.* By Priv.-Doz. Dr. F. Eisler und Dr. G. Kopstein. Leipzig: Georg Thieme. 1931. Pp. 153. M.18.60.

This volume, one of a series intended to cover the whole field of practical radiology, furnishes a very complete review of the examination of the gall-bladder by means of X rays. The authors trace first the history of this method of showing gall-stones, starting from Baxhaum's paper in 1898. A concise account of the anatomy and physiology of the biliary tract follows. In the main section on cholecystography the intravenous, oral, rectal, and intraduodenal methods of introducing the dye are carefully described, and the advantages and disadvantages of each method discussed. The authors themselves prefer the oral method and describe their own technique fully, giving due weight to that followed by other workers. The discussion of interpretation of results is full and clear. Special stress is laid on errors which may arise from variations in the shadow cast by a normal gall-bladder. Faulty projection may produce apparent variations in shape and can only be overcome by great care. The same cause is responsible for some cases where the gall-bladder is described as not filling, and where adhesions are diagnosed. To get the best results the patient must be rotated and films must be taken from different aspects and in different positions; sometimes an opaque meal must be taken before examination if clear-cut results are to be obtained. In our experience this precaution is especially desirable when the mobility of the gall-bladder is in question, since the excursion shown in relation to neighbouring viscera in different postures of the patient is the most reliable evidence of mobility. Hour-glass gall-bladder is fully discussed in all its aspects in this work, with particular reference to its pathological significance. To test the contractility of the gall-bladder the administration of egg yolk is advised, and the authors regard this as an essential part of every cholecystography; we ourselves find that toast with three or four pats of butter is as efficacious and more palatable to most patients. The egg yolk has the advantage, however, that it is more easily included in an opaque meal, if this is found necessary. The authors set out the evidence clearly and dispassionately, and while upholding their own views, do so very fairly and with consideration for those who differ from them. The book is well printed and the illustrations are numerous and well reproduced. The otherwise excellent bibliography is marred by the omission to link up authors named in the text with the corresponding papers quoted in the bibliography. The authors deserve congratulation on a comprehensive and useful monograph.

The Treatment of Behavior Disorders following Encephalitis.

An Experiment in Re-education. By EARL D. BOND, M.D., and KENNETH E. APPEL, M.D. New York: Commonwealth Fund Division of Publications. 1931. Pp. 163. $1.75.

SINCE 1919, when epidemic encephalitis became prominent, it has presented a problem which has perplexed all who have had to attempt to solve it. Teachers, judges, and probation officers, and those in charge of children's institutions, as well as parents, have been mystified when children after this disease suddenly became serious delinquents. The best efforts to handle the problem have been generally unsuccessful.

This book concerns a significant experiment in giving study and treatment to 62 children whose behaviour disorders were the direct result of encephalitis or resembled the effects of that disease. Gathered from homes and institutions where treatment in an adult environment had signally failed, these 62 children became members of a group under the observation and care of the Department for Mental and Nervous Diseases at the Pennsylvania Hospital. In this department the personality of each child is intensively studied; and, guided by the results of the study, attempts are made to develop in the children more wholesome attitudes to their illness and their environment, and to turn their unadaptive apache tendencies into useful, constructive behaviour. Nothing novel in the way of treatment is described. The necessity of having a long-distance plan is stressed, and this plan must be kept in view by all personnel dealing with the child. Such personnel includes psychiatrists, specially trained teachers, nurses, occupational therapists, and social workers. Probably the only criticism that can be offered against this most praiseworthy experiment is on the grounds of expense. Certainly in this country no local authority is likely to consider seriously "a graded school and playgrounds under psychiatric supervision, with a personnel including specially trained teachers, nurses, and occupational therapists" attached to "a hospital for mental diseases with a special building for children in its own grounds." But the methods employed, and the results obtained with this group of "apache" children, should be of considerable help to all concerned with children presenting conduct disorders after encephalitis; and they also throw light upon the treatment of other children whose behaviour is antisocial and perplexing.

A Manual of the Common Contagious Diseases.

By PHILIP MOEN STIMSON, A.B., M.D., Associate in Pediatrics, Cornell University Medical College; Attending Physician, Willard Parker Hospital. Philadelphia: Lea and Febiger. 1931. Pp. 351. $3.75.

THIS book has been prepared for the guidance of medical students, internes, and nurses, whilst the hope is expressed that it will be also of value to general practitioners, pædiatricians, and school physicians. It includes chapters on such subjects as the principles of contagion, serum reactions, and general management of contagious diseases, as well as on all the common infectious diseases except small-pox, the diagnosis of which is, however, dealt with under the differential diagnosis of chicken-pox. In connexion with each disease the rules for the quarantine of school and other contacts are detailed and specific methods of prophylaxis are described. With such a wide field to cover the author has been unable to maintain the balance of his book, and whilst in the chapter dealing with diphtheria such pareses as those of the oculo-motor muscles and the pharyngeal muscles are not mentioned, in the chapter on measles he has thought it necessary to devote two and a half pages to a discussion on the conflicting claims of Tunnicliff, Caronia and Sindoni, and Degkwitz for recognition of the ætiological significance of the various agents they describe. Some useful information may be derived from the sections dealing with the control of contacts of infectious diseases in schools, but since practice in this country seems to differ in several important details from that in the U.S.A., the value of these sections to British readers is somewhat impaired. The chapter on the general management of contagious diseases is concerned mainly with what is designated "medical aseptic technic," and is based on the ritual observed in the Willard Parker Hospital. The "Gown Technic" seems a miracle of completeness and must impose a continuous strain on the aseptic conscience of the nursing staff. Probably a simpler technique combined with attention to such factors as floor space and ventilation would absolve the author from recommending that "measles should be segregated at least on a separate floor, but preferably also in a separate building." Those with experience of chamber isolation wards in this country have had abundant proof that the spread of such diseases as chicken-pox and measles is amenable to that method of isolation. The two chapters on epidemic meningitis and poliomyelitis, in which the author has had the assistance of Dr. Josephine Neal, are the best part of the book. At the end of each chapter is a bibliography, in which we can find references to very little work published outside the United States. The general appearance and printing of the book is excellent, but the various points noted above, together with the fact that the phraseology is liberally interlarded with American idiom, are likely to prevent this work from becoming a serious rival to those already established in this country.

Indian Journal of Medical Research.

IN the April issue (Vol. XVIII., No. 4) R. N. Chopra and V. Iswariah contribute an article on their experimental investigation into the action of the venom of the Indian cobra. S. R. Christophers and I. M. Puri report on the results of their investigations of anopheline mosquitoes collected in Sierra Leone, while J. A. Sinton continues his series in a paper on the identification of *Phlebotomus purii*. An account of the rat-flea survey of Rangoon Port area, which will be read with interest by port sanitarians in particular and by those interested in plague in general, is given by G. G. Jolly, V. W. Fenn, and R. Doral. This account contains graphs and tables, and in their conclusions we note that *Rattus rattus* contributes only 8·83 per cent. to the rat population surveyed. The flea index for *Xenopsylla cheopis* is remarkably low at 0·14, while that of *Xenopsylla astia* is 2·59. C. A. Gill and R. B. Lal give a preliminary report on the epidemiology of cholera. Other papers include one by R. McCarrison, on goitre, and one by L. E. Napier on the feeding habits of sandflies.

of an insured patient's treatment in a rate-aided hospital or his treatment by a private doctor in a nursing home; the risk that remains to be covered is the cost of treatment in a voluntary hospital. Does actuarial information show this cost to be overwhelming when spread over the companies which so serenely encounter the other contingencies of insurance business in this country? As experience accumulates of the working of the compulsory system under Part II. of the Act the companies will doubtless be better able to state the terms on which such insurance can be made complete. At present, the hospitals can fairly contend, there is unfortunately a gap which must somehow be filled.

LATENT MAXILLARY SINUSITIS.

THE term "latent," as applied to any disease, is a relative one, and depends on the available means of examination and on the thoroughness with which they are employed. In the earlier days of rhinology it was used of any case of sinusitis which did not show the frank symptoms of local pain or unmistakable purulent discharge, even when swelling in the region of the middle meatus or a stream of pus could be discerned on expert examination of the nose. With our wider experience such cases can no longer be considered latent, but it has been recognised of recent years that cases of infection of the antrum and other nasal sinuses exist, and indeed are not uncommon, to which the term "latent" may more properly be applied. The symptomatology in these cases is usually that of some secondary complication such as asthma, migraine, retrobulbar neuritis, or the more distant symptoms of a focal infection. Many of the patients have no nasal discharge, except during exacerbations which are described as colds, and the nares look normal on examination. In some of these the antrum is dark, or relatively dull compared with the opposite side, on transillumination, and in many pus or other secretion can be obtained by tapping and washing out, or aspirating, the sinus. It is doubtful whether even these cases should be called latent, for transillumination and exploratory puncture are in everyday use by the rhinologist. But there is a further group of sinuses with chronically infected hyperplastic mucous membrane, or with polypoid degeneration of the lining, which may transmit light normally and from which the washing fluid may return quite clear. It is true that bacteriological examination will here show a growth of pathogenic organisms, but these cases may in the present state of our knowledge be fairly classed as "latent."

It is here that X ray examination has a special diagnostic value, and this is well brought out by Dr. RALSTON PATERSON in an article which appears on another page. Of 100 cases in which the antrum showed clouding on a routine examination, 46 were washed out and pus was obtained in 30, or 65 per cent.; bacteriological examination might well have disclosed a larger proportion of infection. In six of these purulent cases—i.e., in 13 per cent. of those washed out—the sinusitis was totally unsuspected before radiography and they are therefore classed by him as "absolute cases of latent sinusitis," but it is not stated whether any previous rhinological examination had been carried out. There is still a considerable percentage of error both in radiographic and clinical examination. R. A. KERN and H. P. SCHENK,[1] to whose investigations Dr. PATERSON refers, believed that this error was largely due to the rhinologist's reliance on the return of clear fluid on irrigation as an indication of a normal sinus; and certainly increasing experience shows that this is not an entirely reliable criterion without bacteriological examination of the fluid. As we mentioned nearly two years ago,[2] in commenting on their work, a further source of error is that former inflammation may leave a thickening of the muco-periosteum which gives a clouding both in the skiagram and on transillumination. Neither clinical nor radiographic examination is always reliable, but of the two, radiography is the more sensitive. Radiography, however, picks up evidence of past as well as of present disease; furthermore, it often fails to demonstrate recent acute infection, whereas by clinical examination chronic disease is more likely to be overlooked, especially a low-grade type of infection. Both clinical and radiographic methods should be employed in obscure cases, for a sinus cannot properly be regarded as healthy merely because it transilluminates brightly, or even because a clear fluid is returned on irrigation. With the more thorough and accurate methods of examination now at our disposal, fewer cases of sinusitis need be labelled "latent" because they have eluded diagnosis.

HEALTH IN INDUSTRY.

THE general acceptance of the fact that a healthy, contented worker is as necessary to productive efficiency as is well-designed and lubricated machinery is largely due to the activities of the Industrial Health Research Board, whose eleventh annual report has just appeared.[3] The progress made during the second quinquennium of the Board's existence is summarised. The advances recorded are not the less remarkable because they seem obvious when made and are rapidly becoming common knowledge. The ideal work curve, for example, is now recognised. This curve is that of a record-holding long-distance runner who quickly attains his optimum pace and then maintains it unaltered to the end; yet, but a few years ago the saddle-back shape of hourly output, in particular, and other irregular shapes, were claimed to represent normal physiological processes. The discovery of this law of human efficiency—entirely based on the researches of the Board—is to-day of great value in estimating the influence of various factors upon productivity. The value of such adjuvants to output as rest-pauses or improved lighting is measured by the extent to which any particular work curve is made to approximate to the ideal shape. No longer is ridicule poured upon the prophecy that by reducing hours of work output may be increased, in proportion to the extent that output depends mainly upon human activity. In fact the dictum now is that, except to meet some emergency, overtime does not pay; while some daily relaxation is appreciated to be advantageous to both health and efficiency. Accidents have been shown not to be inscrutable acts of blind chance, but to be subservient to definite influences, both intrinsic and extrinsic. Persons of nervous instability display a high accident-rate; 25 per cent. of such persons in any group are likely to be associated with 75 per cent. of the accidents. These unbalanced persons also tend to have a high sickness-rate, and to be the least skilled among the workers. Extrinsic factors are also important. Fewest accidents occur at a temperature of 65°–67° F., which is the optimum for output and for least lost time; the accident-rate is also affected by lighting, noise, and external irritations. In fact, the incidence of industrial accidents may be used to measure healthy or unhealthy industrial environment. Here, then, is another discovery—that, given the existence of a hazard, accidents are not "accidents."

[2] THE LANCET, 1929, ii., 779.

[3] Eleventh Annual Report of the Industrial Health Research Board to June 30th, 1931. H.M. Stationery Office. 1931. 1s. 6d.

All research, however, has not been positive; certain ghosts have been laid. The effect of monotonous repetition work is one; it has often been claimed as a soul-destroying influence of modern mass production. Nowadays it is known that boredom is more intense in semi-automatic operations, which prevent freedom of thought, but are insufficient to keep the mind fully occupied; relief comes from more complete mechanisation, when the mind may wander. Nevertheless, the more intelligent workers prefer occupation which keeps both body and mind fully employed. Another bogy exposed is the harmful influence generally held to be exerted by menstruation on mental and muscular efficiency; the undue stress laid on this influence amounts often to an obsession. Research has failed to provide experimental evidence that the menstrual period in normal women is associated with serious incapacity; it rather indicates that no special strain is laid upon the organism by the performance of physical work at such times, and, since functional activity, as a whole, is lowered, that external work is performed at lower physiological cost. These findings are in accord with the survey reported in this journal last July,[4] which disclosed that certainly more than half a typical batch of schoolgirls have no pain or disability at all at a time when popular tradition pictures their lives as profoundly disturbed; while the association disclosed between active exercise and "no pain" recalls the advice given in the seventeenth century by RAMAZZINI to his fashionable patients who complained of dysmenorrhœa, to follow the customs of working women.

A final example of the negative results recorded by the workers of the Industrial Health Research Board is the refutation of the assertion, often made, that the conditions of so-called humid weaving sheds are less favourable than those of other sheds; here the most careful analysis of invalidity records has failed to supply any evidence in support of the contention. Many other features are summarised in the report, all of practical economic advantage to our industries. References are supplied to the original accounts of the investigations, and these deserve the attention of works-managers, as well as their medical advisers.

ANNOTATIONS

DETECTION OF BACTERIA IN MILK.

AN indictment of official methods of testing the bacteriological content of milk is made by Prof. James McIntosh and Dr. Lionel Whitby in our columns this week. As the outcome of investigations, extending over six years, on the milk supplied to the Middlesex Hospital, they criticise not only the standard technique of estimating bacterial content but the popular "holding" method of pasteurisation, and they emphasise the necessity for continuous as distinct from intermittent bacteriological control. Their contention is that on the whole the expensive high-grade products are outside the purse of the average hospital, and that for an institution the problem resolves itself into the purchase of milk of good average nutritional value. The examinations recorded in this article are mainly of samples of ordinary milk before and after pasteurisation, and of milk supplied to the hospital as pasteurised milk. In view of their bacterial findings on milk pasteurised by the "holding" method, they submit that the "flash" method is preferable. This view was formed after examination of samples sold to the hospitals as "pasteurised milk"—that is milk which under Milk (Special Designations) Order, should not contain more than 100,000 organisms per c.cm. During the warm weather, May to September, these samples have often been found to have a bacterial content of several millions. Furthermore, many millions of viable organisms per c.cm. were found in some samples of pasteurised milk sent to these authors for examination in the summer of 1928 by the M.O.H. of Islington. The results of the analyses "came as a bombshell" to the dairy company concerned, which is known to take great pains to supply the public with clean and wholesome milk. A very opportunity was given for confirmation and comparison of results, and eventually the discrepancies were traced to a difference in the technique of the examination, the Middlesex Hospital workers having used a richer medium than that recommended in the Circular issued by the Ministry of Health. The main thesis of their important communication is that a richer medium should be officially adopted for routine examination, since bacteria which resist the "holding" method of pasteurisation in common use may escape detection when cultures are made on the lemco-peptone agar at present recommended by the Ministry. The preference expressed for flash pasteurisation follows naturally on the smaller numbers of bacteria obtained from samples of milk thus pasteurised.

TUBERCULOUS BACILLÆMIA IN ACUTE RHEUMATISM.

For many years now in Vienna blood cultures for tubercle bacilli have been made by Prof. E. Loewenstein; the blood of at least 4000 cases has been examined, and from these experiments the following facts have emerged. In healthy persons tubercle bacilli have never been found, nor are they found in the blood of patients with carcinoma, sepsis, enteric fever, pneumonia, or venereal diseases. Tubercle bacilli can be found at times in the blood of all progressive forms of tuberculosis, especially during exacerbations. This is true not only of pulmonary tuberculosis but also of tuberculosis of the skin, larynx, kidney, and eye. For instance, in tuberculous skin lesions—tuberculides, Bazin's disease, lupus erythematoides, &c.—according to the latest reports positive blood cultures have been obtained in 51 of 92 cases (55 per cent.);[1] the figures available when we last commented on this work (see The Lancet, May 23rd, 1931, p. 1147) were 41 positives out of 66 cultures made in cases of tuberculous skin lesion—that is, 62 per cent. Another important fact that emerges is that tubercle bacilli seem to be found with a very considerable frequency in diseases which till now were not commonly regarded as tuberculous in origin. In so-called acute rheumatic polyarthritis positive blood cultures have recently been obtained in at least 24 cases; within the short space of four months seven young women was admitted to one clinic in Vienna with typical rheumatic joint and cardiac lesions, showing tubercle bacilli in the blood, in some cases cultured on several occasions.[2] In children with acute rheumatism, pure cultures of tubercle bacilli, pathogenic to rabbits, fowls, and guinea-pigs, were frequently obtained. And now[3] Loewenstein describes his success in obtaining four positive blood cultures from cases of chorea; 17 positive blood cultures from 40 cases of disseminated sclerosis; in cases of retrobulbar neuritis 4 out of 6 cultures made were positive, and in cases of schizophrenia 9 out of 24. It is admitted that 7 of the 17 cases of disseminated sclerosis had signs of pulmonary disease, and one case at autopsy showed obvious pulmonary tuberculosis. This resemblance between rheumatism and tuberculosis has long been a matter of comment. Poncet, in 1909, described cases of tuberculous rheumatism, and many suggestive cases have since been published, especially in France. A short description of this relationship, with references, can be found in Recent Advances in the Study of Rheumatism (London, 1930), although the authors do not mention Loewenstein's work. Another curious link between acute rheumatism and tuberculosis is in connexion with the disputed ætiology of erythema nodosum. Loewenstein has shown that in tuberculosis positive cultures are found in the spring rather than in the autumn and winter. Forty patients with skin tuberculosis, in whom blood cultures were made every two to three months, were followed up for a period of one and a half years. A few were persistently positive, but the majority became negative in autumn and winter, only to relapse in the following spring. Is the seasonal incidence of rheumatism and chorea to be explained on similar lines? Are the exacerbations and recrudescences to be attributed to a tuberculous bacillæmia? Although tubercle bacilli have been cultured from the blood in cases of so-called rheumatic arthritis, morbid anatomy and histology do not support the view that tuberculosis is the pathological basis of a polyarthritis or carditis. Tuberculosis, especially of a severe degree, has always been rife in Vienna, although it must be noted that in the cases of skin tuberculosis the blood for Loewenstein's investigations was taken from patients all over Europe, in cities as far apart as Hamburg, Bergen, and Copenhagen. A curious feature of Loewenstein's rheumatic cases with a positive blood culture was that the Pirquet and Mantoux tests were frequently negative, although, according to many authorities, a tuberculous bacillæmia is necessary for the establishment of allergy to tuberculosis. Loewenstein's work does not depend merely on the demonstration of stained tubercle bacilli, but on their actual culture from the blood, and since his technique is apparently not difficult, it is highly desirable that his work should be repeated in this country.

CLIMATOLOGY IN MEDICINE.

The medicine of a hundred years ago made use of remedies very like those of the present day—namely, drugs, diet, and environmental and physical influences such as climate and baths. With intensive use of the experimental method has come a better understanding of the effect of drugs and diet, and besides leading to the discovery of new remedies this has shown the correct application of old ones, so that results can now be predicted which were previously uncertain. So far from disproving the efficacy of the older forms of treatment, however, modern experiment has usually served rather to show their true basis while at the same time defining their purpose and limitations.

With the advent of this new knowledge of diet and drugs, climatic therapy has fallen somewhat into the background. Despite countless observations on many of the factors at work—such as air temperature and moisture—there is as yet little correlation of these data with physiological reactions, and there are probably many factors involved which are at present imperfectly understood. In Germany climatic and spa treatment has always taken a relatively important place, and the movement towards their scientific study has lately been conspicuous there. The many papers appearing in the German medical press this year show clearly, however, that climatic therapy is still mainly in the empirical stage. The difficulty of adapting the experimental method, as A. Loewy[1] points out, is the large number of variables not under direct control as in laboratory conditions. Then again the climatic conditions regarded as typical of a certain locality are constantly being upset by temporary weather effects. Thus sea air increases the respiratory exchange and the metabolic rate,[2] but a person residing on the coast is only thus influenced, it is said, as long as the sea wind is blowing. Again, heat loss depends not merely on air temperature, but also on ground temperature and wind speed. Thus localities where the cooling values, as estimated instrumentally, are similar, may have widely different climatic conditions. The most definitely known effects at present, apart from ultra-violet radiation, are those of high altitudes, where oxygen-lack stimulates respiration, increases hæmoglobin, and raises the blood pressure. Sea air also has a stimulating effect, and there are indications that the particulate matter especially present in the air of low-lying inland places may be of importance by virtue of its chemical nature or electrical charge. In this as in other branches of medicine much is known, but little is yet applicable to practical therapeutics. In addition to studying the types of climate there should be a more determined attempt to assess the results of treatment of certain diseases under different climatic conditions. This experiment would have to be done on a large scale if the results were to be of any value, but there is at least a big field open here for those who have the necessary opportunities.

RECENT WORK ON DIPHTHERIA.

THE May issue of *Annales de Médecine,* which has lately reached us, contains 13 papers, from eight different countries, on the epidemiological, bacteriological, and clinical aspects of diphtheria. In a short note on experience in Paris during the last five years Émile Roux points out that though cases of malignant diphtheria have been more numerous in France, as in other European countries, since 1926, in Paris the case mortality during this period has been comparatively low, and there has been no increase in the incidence of the disease. He emphasises the importance of early administration of antitoxin, which, he maintains, it is a mistake to regard as curative, its action being merely to prevent the spread of intoxication. J. von Bokay gives a short history of diphtheria at Budapest since 1884, when the disease was first made notifiable, and draws attention to the increased severity and prevalence of faucial attacks, whereas there has been a considerable fall in the incidence of laryngeal cases. In a biological and immunological study R. Debré, G. Ramon, and P. L. Thiroloix come to the conclusion that the severe forms of diphtheria, especially those which end fatally, are produced by organisms with a remarkably high pathogenic power, although they admit that individual resistance, as determined by estimation of the antitoxin in the blood, must also be considered. In their paper on the general character of diphtheria in the French army since the war, C. Dopter and Collignon show that diphtheria has increased during this period in the army, as in the civilian population, especially in certain garrisons. Systematic active immunisation, however, has had such an excellent effect in reducing the incidence that a Bill is being prepared to make this practice compulsory, as has been done in the case of inoculation against typhoid fever. In a paper on latent infection in diphtheria, U. Friedemann, of Berlin, maintains that the influence of latent immunisation on the incidence of diphtheria is greater for diphtheria than for scarlet fever, but less than for poliomyelitis, diphtheria being an endemic disease in all civilised countries, in contrast with poliomyelitis, which is essentially an epidemic disease. E. Gorter describes a severe epidemic at Leyden, in 1930, characterised by a predominance of toxic cases and an unusual frequency of subsequent paralysis. Prof. and Madame Hirszfeld, of Warsaw, discuss the constitutional basis of the Schick reaction, and refer to their researches showing that if both parents have a positive reaction the reaction is almost always positive in their children, while if the parents have a negative reaction, two-thirds of the children are negative and one-third positive, and, lastly, if one parent is positive and the other negative 56 per cent. of the children are positive.

P. Lereboullet, J. J. Gournay, and J. Donato, who discuss the renal function in diphtheria with a record of eight illustrative cases, come to the conclusion that renal involvement, as shown by hyperazotæmia and albuminuria, does take place in diphtheria, but that clinical, anatomical, and experimental evidence does not favour the view that this involvement is so serious as in scarlet fever, and, in any case, it is much less important than affection of the heart, suprarenals, and central nervous system.

In an article on the serum treatment of diphtheria, Ramon and Debré hold that the charges of inadequacy brought against diphtheria antitoxin in the recent severe outbreak of diphtheria on the Continent are not justified, and incriminate the malignancy of the attack, delay in administration of antitoxin, and association with other infections, as responsible for its apparent failure. They add that the generalisation of active immunisation by anatoxin is the only certain method of protection against diphtheria. H. Roger, C. Mattei, and J. Paillas, who have collected 70 cases of paralysis of the brachial plexus following serum treatment of any kind, emphasise the rarity of this sequel, especially in the case of diphtheria antitoxin, of which only nine examples have been recorded, in contrast with 40 following injection of tetanus antitoxin. Bela Schick and Anne Topper, of New York, confirm their previous observations, showing that tonsillectomy and adenoidectomy tend to convert a positive Schick reaction into a negative one, and thus increase immunity to diphtheria. They suggest that children with diseased tonsils, who are hypersensitive to horse serum, should have them removed, and that children who have undergone tonsillectomy within the last six months should be Schick-tested before being immunised by toxin-antitoxin, or anatoxin. S. Schmidt, of the Danish Serological Institute, deals with the affinity between toxins and their specific antitoxins. The history of diphtheria in Berlin is narrated by E. Seligmann, who deals especially with the remarkable recent increase in its severity, the case mortality having risen from 5·8 per cent. in 1924 to 11 per cent. in 1927, and being almost as high in school-children as in younger patients. Like the other writers, he insists on the value and harmlessness of active immunisation.

EPHEDRINE.

THE purpose of the series called "Medicine Monographs" is to provide, in convenient and readable form, critical digests of recent views on various aspects of medicine. Volume XVII. on "Ephedrine and Related Substances"[1] adequately fulfils that purpose. The teacher and clinician will welcome a succinct account of the history, pharmacognosy, and chemistry of the genus ephedra, and the pharmacological action and therapeutic uses of ephedrine, by one who has been mainly responsible for extending our knowledge of this important drug. The laboratory worker will be interested especially in the questions raised by the work on ephedrine and related substances regarding the difficult problem of the relation of chemical composition to pharmacological action, and the incompleteness of our knowledge of the mode of action of sympathomimetic drugs. He will also find of great value the compilation of published papers on the subject. A curious fact, not generally known, is that though ephedrine has only recently risen to popularity, and thus justified the traditional faith of the Chinese in one of their ancient remedies, the drug was known and experimented with 30 years before its possibilities were appreciated. At that time only toxic doses were employed, and the drug was set aside as being unlikely to be of value. Dr. Chen's work showed more clearly its true action. It resembles adrenalin, in that, in suitable doses, it raises the blood pressure, increases cardiac activity, relieves broncho-spasm, and dilates the pupil, while it more frequently inhibits than stimulates the gastro-intestinal tract. It has, however, the special advantage over adrenalin in that it is a stable substance. Its solutions do not decompose on exposure to air, light, or heat, or by long standing. It is easily absorbed, and has a low toxicity. It can be applied locally; and since it is not destroyed by the gastro-intestinal secretions it is active when given by the mouth as well as by subcutaneous injection. Because of these actions it has found many clinical uses, but the review suggests that it is especially valuable in relieving spasm of the bronchial muscle in such conditions as bronchial asthma, hay-fever, bronchitis, and whooping-cough, in combating the fall of blood pressure in spinal anæsthesia, and in shrinking the congested nasal mucous membrane. The introduction of ephedrine into the clinic is an important contribution to symptomatic treatment, but the remedy is not ideal, for it may produce side-effects, such as palpitation, trembling, faintness, and insomnia. Some of these symptoms are perhaps inevitable with a drug which has the general pharmacological action of ephedrine, but there is hope that important progress will be made in the search for related substances which will have all its advantages and none of its drawbacks.

FOREIGN BODIES IN THE EAR AND NOSE.

AMONG 15,000 children examined at a clinic for nose, throat, and ear defects, Mr. J. A. Keen [1] found 73 cases of foreign bodies in the nose or ears—an incidence of rather less than 0·5 per cent. All but two came to the clinic for some other reason. Of foreign bodies in the ears, the commonest (22 out of 43) were small pieces of cotton-wool deep in the meatus, usually beyond the isthmus. Removal with fine dressing forceps is easy, but syringing often fails to dislodge them and forcible syringing is not, of course, advisable in the presence of otorrhœa. Often removal of the wool stopped a discharge which had been unsuccessfully treated for weeks. The other foreign bodies (21 cases) included cardboard, beads, slate pencils, and crayons. Glass beads were particularly difficult to remove and the best instrument was found to be a malleable silver probe, whose end could be bent into a fine hook which could be slipped into the eye of the bead. A small foreign body which has been in the meatus for some time becomes surrounded by cerumen and its presence is not suspected. In no case in this series was operation needed, as it sometimes is in children under four, but occasionally an anæsthetic was required. Most of the 30 foreign bodies in the nose were beads and buttons, but one was a pure rhinolith. About half the children were dealt with in the out-patients' department, a little 10 per cent. cocaine solution being applied to the septum and the anterior part of the inferior turbinals. The instrument used was the malleable probe introduced above the foreign body and worked downwards, or the ordinary nasal dressing forceps. One case was the starting point of a long and fatal illness resembling the rare disease described as rhinitis caseosa by StClair Thomson. The most important aspect of foreign bodies in the nose, however, is their association with nasal diphtheria. Burton and Balmain [2] say that in children suffering from a chronic unilateral nasal discharge (sent to isolation hospital because a nasal swab is positive to the Klebs-Löffler bacillus), this association is common. These children did not suffer from clinical diphtheria, though they may be carriers, and the nasal diphtheria is cured by the removal of the foreign body. Mr. Keen admits that text-books advise that a culture of the nasal secretion should be taken before removal of a foreign body, but in his experience this is not advantageous.

RAMISECTION IN SPASTIC WEAKNESS.

JUST a year ago we published a paper [1] by a group of London orthopædists and neurologists in which they described six cases operated on by Mr. N. D. Royle for spastic weakness, and gave their opinion that the operation appears to have no place in the treatment of this condition. It will be recalled that this verdict was by no means accepted by Mr. Royle,[2] nor by some of his supporters in Australia and America. Accordingly, the Royal College of Surgeons of Australasia, at its annual meeting, has appointed a committee to investigate in Victoria the condition of patients on whom the operation has been performed. The members [3] are Prof. F. Wood Jones, F.R.S. (chairman), Sir Richard Stawell, Dr. Fay Maclure, Dr. H. C. Trumble, Dr. A. E. Coates, Dr. J. B. Colquhoun, and Dr. H. F. Maudsley. Another committee is to report on cases in New South Wales.

HEAD MURMURS.

Dr. Louis Hamburger [4] revives the interesting subject of auscultation of the head. As long ago as 1833, he says, Dr. John Fisher suggested that auscultation might prove an important means of diagnosis of cerebral diseases, but for many years little attention was given to it.

The murmurs, Hamburger points out, may be either intracranial, extracranial, or infracranial in origin. Of the first group—those arising inside the skull—the systolic murmurs of childhood are pretty well known. They may be heard especially during the second year of life, and not infrequently below this age. They may be detected in quite healthy babies, but are very seldom heard after the age of four, and almost never persist into adult life. Anæmia and rickets are thought to be contributory factors in their causation, but the way in which they arise is not exactly explained. Hamburger, however, feels sure that they are without pathological significance, and suggests that frequent examination for them would more often demonstrate their presence. At the same time it might occasionally give rise to needless despondency, as apparently happened in a case which he mentions. The second group of murmurs are those accompanying arterio-venous aneurysms, and though, of course, rare, they are well recognised as arising either from trauma or "spontaneously," in which case they are often congenital. The latter group may be due to aneurysmal angiomata; the former may result, as in cases of "pulsating exophthalmos," from a communication between the internal carotid artery and the cavernous sinus, following fracture of the base of the skull. Such, however, are real surgical rarities. A third group of murmurs are those found with intracranial tumours, such as meningiomas and gliomas, but they are exceedingly rare, whilst in uncomplicated intracranial aneurysms a murmur is almost never present. Occasionally there may be vascular communications between the external and internal blood-supply of the skull, producing a murmur on auscultation. In the final group of cases head murmurs are conducted upwards from the carotids, and include those occurring in severe arterio-sclerosis, in exophthalmic goitre, and sometimes with valvular disease of the heart. These may be noticeable to the patient as well as to the observer.

As a rule the detection of a cephalic murmur is of academic rather than practical importance, though in the diagnosis of arterio-venous aneurysm or angiomata it may be of great value. A revival of cephalic auscultation, in the absence of a full realisation of its limitations, would add to the anxieties of practitioners, without much increasing the information at their command.

VENEREAL DISEASE IN THE BRITISH EMPIRE

THE fifth Imperial Social Hygiene Congress organised by the British Social Hygiene Council opened in London on July 13th under the chairmanship of Mr. L. S. Amery, and the first day was devoted to a review of social hygiene and venereal disease throughout the Empire. Dr. David Lees, chairman of the medical advisory board of the Council, remarked that every country in the world contains enough infected people to constitute a grave problem. There were, he said, striking examples—in Cyprus, Malaya, and Madras, for instance—of what could be attained in spite of great difficulties by careful expenditure on the three essential methods of combating venereal disease: education and public enlightenment; free and efficient treatment; and an adequate staff able to deal with the problem sympathetically and from a public health point of view. Legislative measures, in his opinion, had not been in force long enough to allow a fair estimate of their success. Nevertheless the representatives of Australia and New Zealand maintained that the legislative enactments in those countries had yielded highly satisfactory results. Dr. F. McCallum, reading a paper by Dr. M. J. Holmes, Director of the Division of Tuberculosis and Venereal Disease, said that in Australia the control of the disease was based on treatment by qualified medical men only; an obligation on sufferers to place themselves under treatment without delay; a written warning of the consequences and dangers of the disease, handed to the patient by the doctor; compulsory, impersonal, and confidential notification; and personal but confidential notification of default. Similar regulations are in force in New Zealand, where gonorrhœa and syphilis were declared in 1924 to be infectious diseases, thus giving the Department of Health the same powers as in dealing with other infectious diseases—viz., the power to order an infected person to hospital and to institute legal proceedings against anyone who wilfully permits or suffers any act likely to infect another. Dr. Bernard Myers, presenting a report by Dr. Watt, Director-General of Health for New Zealand, endorsed this encouraging view of legislation but commented on weak spots in the system: fictitious names and addresses given by patients; treatment of venereal disease by chemists; and the failure of medical practitioners to comply strictly with the law. It is hoped that the ethical bodies of the doctors and pharmacists will be able to deal with this trouble.

Among the many reports presented from other Dominions and Colonies, India was represented by that of Col. A. J. H. Russell, and Madras in particular by a report from the Surgeon-General. Unfortunately in many parts of India "financial stringency"—a false view of economy, as many would say—has prevented progress. There is still a great lack of welfare work among sailors, particularly Indian sailors, in the ports, and salvarsan and kindred drugs have not yet been exempted from customs duty. Sir Ronald Storrs gave an account of his experience with a military government in Jerusalem. The brothels had been immediately closed throughout Judea and their occupant repatriated; a women's social council had been formed and a social welfare worker appointed. In Cyprus the Government had appointed a social hygiene council, a venereologist, a bacteriologist, and a social worker, and there had been a steady arousal of interest among the women of Cyprus. The Cyprus clinics were now the best in the world, because the most recent. In three years 12,000 cases had been treated and a reduction of 32 per cent. in the incidence had been effected. In Basutoland, Dr. K. H. Dyke reported that an average of 7000 new out-patients are seen in the dispensaries every year and syphilis is widely prevalent. One of the chief troubles of the district is that the natives have no dread of the diseases, but fortunately they like having injections and it is therefore easy to use the sulfarsenol which the Government has provided this year. The treatment of gonorrhœa has not been attacked actively. In Zanzibar Dr. S. M. Vassallo finds a curious mixture of modesty and the reverse. Modesty unfortunately begins with the necessity for treatment, and, although inoculation has made a great impression on the natives' imagination, this effect has the disadvantage that they expect inoculation for everything. Dr. R. S. Taylor ascribed a great increase in venereal disease in Somaliland to famine, which had driven women to vice. Dr. J. W. Graham, medical officer of Tanganyika Territory, declared that the future of Africa was in the hands of the women. With their emancipation the social customs of the Africans would be greatly improved.

The Conference continues throughout the week and other aspects of the problem are being discussed.

A NEW FLOCCULATION TEST.

FLOCCULATION tests for syphilis which depend on the fact that precipitation occurs when a syphilitic serum is treated with organ extracts, are of most use in treated cases of syphilis where they remain positive longer than the Wassermann reaction does. It would appear that more lasting results are obtained when the duration of treatment is controlled by application of a flocculation test. In the most recent comparative survey of the value of the different flocculation tests with known sera,[1] the Kahn test produced the most satisfactory results, giving no false positives and showing itself to be more sensitive than the Wassermann reaction in treated cases. The Vernes reaction presents a theoretical advance on the other methods inasmuch as it minimises the personal error by introducing mechanical mixers and photometric readings. This reaction fails, however, in comparison with other flocculation tests because of the expensive apparatus required and because it is certainly not less sensitive to treatment than the Wassermann reaction. In the newer tests the Meinicke clarification reaction and the Kline show great promise since they give a high degree of agreement with the minimum of manipulation. For the new Meinicke test it is claimed that hæmolytic, icteric, and cloudy sera are all adaptable to the reaction, and that a falsely positive result can never be produced by the admixture of blood or other contaminations with the sera. It is a modification of the author's turbidity reaction and was first described by him in 1929. Dr. W. Ogden and Mr. F. Partner, working at the Central Pathological Laboratory of the London County Council Mental Hospitals, have compared the new Meinicke clarification reaction with the Wassermann reaction and find total agreement in 96·6 per cent. of sera. (see p. 121). Of those sera showing disagreement the results were in favour of the Meinicke. This test is said to be easy to read and can be performed rapidly with small quantities of serum (micro-reaction), though the macro-reaction is regarded as more reliable. It is held to be desirable that workers using this test should adhere to the method described by its originator.

---

[1] Brit. Jour. Vener. Dis., 1931, vol. vii., No. 2.

TREATMENT OF HICCUP.

PERSISTENT hiccup, which may cause much discomfort and distress and even endanger life, is often difficult to relieve. R. F. Sheldon[1] amongst others has shown that carbon dioxide inhalation, by its direct action on the respiratory centre, is the most reliable means of re-establishing normal breathing. A great objection to this form of treatment is, of course, the need for cumbersome and expensive apparatus. L. A. Golden,[2] however, uses an ordinary paper bag which is placed tightly over the mouth and nose. The patient is instructed to breathe into the bag, and by rebreathing his expired air raises the concentration of carbon dioxide in his blood until, in five minutes or so, the spasmodic inspirations are replaced by regular ones.

THE SELECTION OF OUT-PATIENTS.

IT was to be anticipated that one of the most interesting discussions at the recent joint conference of the British Hospitals Association and the Incorporated Association of Hospital Officers at Eastbourne was that which dealt with the out-patient department.[3] The voluntary hospitals are having to cope with an almost alarming increase, not only in the number of out-patients, but in the ratio of their attendances. Since 1920 the out-patients of the London teaching hospitals have grown by something approaching 10 per cent. in number and by close upon three times that percentage in attendances. These attendances are now little short of four millions in this group of hospitals alone, and almost every annual report from institutions all over the country records a corresponding increase. The papers which formed the basis of the discussion were read by Mr. W. Parkes, the secretary of St. Mary's Hospital, Paddington, and Mr. W. McAdam Eccles, consulting surgeon to St. Bartholomew's Hospital, whose joint experiences cover the administrative and the medical aspects of this subject. There was general agreement both in the addresses and in the discussion that, although, except as regards chronic cases, there is not much real abuse of the out-patient system, some means of limiting the numbers will have to be found, not less for the sake of the medical staff than of the patients. The limitation must not be too rigid. Access to a hospital must be reasonably easy, and, as Mr. Eccles put it, it is essential that there should be "a good and varied supply of out-patient material for teaching purposes."

The crucial question is how this limitation is to be brought about. To eliminate the "chronic ordinary" is clearly the first step—if an out-patient department is to be a real consultative centre he is matter out of place, standing in the way of those who are really in need of specialised advice and treatment. The recommendation that a doctor's letter should be an essential passport for an out-patient department appears to have obtained something less than general assent at the conference; the alternative is a laborious winnowing process at the hands of the medical staff and their assistants. Closer understanding and coöperation between local medical practitioners and the hospital staffs would obviously make it easier to discriminate cases needing help from a consultant, though this does not imply refusal to admit the right of the remainder to present themselves at the hospital. The voluntary hospitals cannot risk getting a bad name because their rules are too rigid in this respect. But the present unorganised system not only invites abuse, but entails another form of discipline more irksome sometimes than exclusion. The dreary wait in the out-patients' department will have to be mitigated somehow. We drew attention recently[1] to the efforts made in some hospitals to make and keep appointments, pointing out that such appointments can be made for small groups rather than individuals to secure continuity of attendance without gaps. The careful reorganisation involved would be repaid in the better atmosphere, and possibly even in increased donations from those who appreciate being treated with consideration.

AN APOLOGY.

BY the courtesy of the Board of Control a proof the Annual Report for 1930 was sent to THE LANC in common with other medical journals. Such advan information is supplied in order to allow sufficient time for perusal before publication of the Report, on the understanding that no comment will be made before a copy is received from H.M. Stationery Office. By a series of mischances the usual precautions against premature publication proved ineffective, and a notice of the Report, which has not yet been issued, appeared in THE LANCET on July 11th. We greatly regret this unfortunate incident, and offer full apologies to the Board.

WE have to announce the death of Mr. Francis Richardson Cross at Clifton, on Sunday last, at the age of 83. Mr. Cross was consulting ophthalmic surgeon to the Bristol Royal Infirmary and a former President of the Ophthalmological Society. He served on the Council of the Royal College of Surgeons of England for 16 years.

INDEX TO "THE LANCET," VOL. I., 1931.

THE Index and Title-page to Vol. I., 1931, which was completed with the issue of June 27th, is now in preparation. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 7, Adam-street, Adelphi, W.C.2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

MODERN TECHNIQUE IN TREATMENT

A Series of Special Articles, contributed by invitation.

CCCXVII.

THE TREATMENT OF
DYSHIDROSIS OR CHEIROPOMPHOLYX.

DYSHIDROSIS was first described by Tilbury Fox and at about the same time by Hutchinson who named it cheiropompholyx. From that time to the present day the condition has been the subject of lively controversy in all parts of the world. The eruption, which is accompanied by considerable itching, occurs chiefly on the lateral aspects of the fingers and toes, and on the palms and soles, though it may involve also the dorsal aspects of the toes, feet, and hands, and occasionally may extend to the wrists and forearms. It consists of pearly vesicles embedded in the epidermis which in severe cases may become confluent to form bullæ of considerable size. In the palms and soles the vesicles are deeply situated, and owing to the thickness of the overlying horny layer they seldom rupture. They feel shotty and have aptly been compared to sago grains embedded in the skin. In mild cases the lateral aspects of the fingers only may be affected. Dyshidrosis occurs, as a rule, in hot weather and affects chiefly subjects who sweat freely. The duration of an attack varies from three to six weeks. While the acute vesicular stage is usually over in from 10 to 14 days, a desquamative stage follows which may last for several weeks.

Dyshidrosis Complicating Recognised Dermatoses.

As the name implies, Tilbury Fox regarded dyshidrosis as a disorder of the sweat apparatus, but this view lost favour as the result of further studies by English and Continental investigators, who found no pathological evidence of damage to the sweat glands or their ducts. At the present moment there are some who, doubting its existence as a clinical entity, believe that dyshidrosis is merely a special aspect of a number of well-known dermatoses. The following case illustrates this point of view. An elderly lady had suffered for about a year from attacks of typical dyshidrosis affecting especially the hands. She had undergone treatment at a Continental spa without relief. The cause was discovered in a very chronic interdigital ringworm infection of the toes. Examples of this kind could be multiplied indefinitely.

An examination for fungus should be made in every case of dyshidrosis. The cause is usually the *Epidermophyton inguinale*, a fungus which has a predilection for moist intertriginous surfaces. The toes are very commonly attacked and in this situation the infection is nearly always chronic. The fungus secretes an endotoxin which entering the blood stream gives rise to a dyshidrosiform eruption on the hands. This mechanism has been demonstrated by human experiment and explains the frequent absence of fungus in the acute vesicular eruption of the hands. The acute vesicular eruption may, on the other hand, be due to direct infection.

Ringworm infection disposes of an important proportion of the cases of dyshidrosis. The thrush fungus *Monilia albicans* is also capable of causing dyshidrosis, and recognition of its importance is growing. A number of exogenous irritants may produce a condition objectively identical with dyshidrosis. The subjects attacked are chiefly those who suffer from hyperhidrosis of the palms and soles. The hands are attacked first and, by a mechanism not yet explained, the feet often follow suit. The exogenous origin is elucidated by careful inquiry regarding the patient's occupation.

Dyshidrosis may be a manifestation of seborrhœic eczema. It is well recognised that chronic seborrhœic eczema of the scalp and of other parts may be accompanied by an eruption of the palms and soles identical with dyshidrosis. Dyshidrosis may accompany seborrhœa, or seborrhœa with dandruff, but here it is perhaps a question of true dyshidrosis. Dyshidrosis may be a manifestation of eczema of any type, for example, chronic varicose eczema, pruritus ani, with eczematization, &c. In such cases dyshidrosis is probably due to sensitisation of the skin of the palms and soles by the products of tissue autolysis derived from the chronic foci.

True Dyshidrosis.

Having thus considered the cases of dyshidrosis complicating well-known dermatoses it is necessary to inquire whether there are any left which may be regarded as true dyshidrosis. The question may be answered by stating an indisputable fact—namely, that there are many who, in the complete absence of any of the causes already enumerated, develop dyshidrosis every summer or even at intervals throughout the year. Further, the attacks follow the typical course already described lasting from three to six weeks, though many mild cases affecting only the fingers are known. Almost all cases have hyperhidrosis. It is, in fact, probable that the conception of Tilbury Fox will prove eventually correct and that time will demonstrate beyond doubt the existence of a true dyshidrosis and of a causal disorder of the sweat apparatus. Evidence of such a disturbance has already been reaffirmed by Sicoli, who has demonstrated dilatation with occasional rupture of the intra-epidermal portion of the sweat ducts, in cases of dyshidrosis. Unfortunately, owing to the difficulty of collecting sweat in adequate quantities, its chemical composition in normal and in pathological states such as dyshidrosis does not yet appear to have been the subject of important study. It is, however, known that variations in its composition occur under varying physiological conditions—for example, lactic acid is excreted in quantity at certain stages of muscular training. While mere mechanical dilatation of the sweat ducts due to explosive secretion of sweat as suggested by Sicoli may not prove the whole explanation of dyshidrosis, it is possible that future studies of the chemistry of sweat may provide a further clue to its pathogenesis.

It is clear that the diagnosis can only be made by exclusion. It may not be difficult to eliminate the cases of dyshidrosiform eruptions due to obvious exogenous causes or those which accompany eczema of other parts; the treatment of such cases must be that of the cause. But it may be extremely difficult, when the eruption is limited to the palms and soles, to eliminate fungus infection. Indeed so many cases of dyshidrosis are caused by ringworm infection that it is desirable to consider the treatment of the disease under two headings: (1) mycotic dyshidrosis; (2) true dyshidrosis.

Mycotic Dyshidrosis.

Regarding dyshidrosis as a special type of eczematous reaction, it is a remarkable fact that cases of mycotic origin will tolerate strong fungicidal preparations that would be harmful in non-mycotic or true dyshidrosis. When the presence of *Epidermophyton interdigitale* has been demonstrated one should not hesitate to attack it vigorously. The interdigital spaces should receive the greatest attention, and it is important to realise that the infection is nearly always difficult to cure in this position; it may, in fact, be of life-long duration. The spaces are generally lined with tough dead white sodden epidermis, and the fungus proliferates freely beneath this protective covering, to remove which strong keratolytic preparations are necessary. Whitfield's benzoic and salicylic acid ointment may be effective :—

Benzoic acid	grs. 25
Salicylic acid	grs. 15
Soft paraffin	drs. 2
Coconut oil	to 1 oz.

or the following paint also suggested by Whitfield :—

Benzoic acid	grs. 25
Salicylic acid	grs. 15
Acetone..	drs. 2
Spirit	to 1 oz.

Sabouraud recommends the preliminary application of a depilatory paste, e.g. :—

Barium sulphide	1	
Quicklime	10	
Rice starch	10	(Darier)

to be mixed with a little glycerin to make a paste and applied from half to three-quarters of an hour daily.

He states he has succeeded in curing interdigital epidermophytosis only by such preliminary treatment.

After the horny debris has been thoroughly softened and removed a paint may be applied twice daily :—

Chrysarobin	dr. 1
Acetone	drs. 4
Spirit	to 1 oz.

or carbol fuchsin paint (Castellani) :—

Saturated alcoholic solution of basic fuchsin 10 c.cm.
Five per cent. aqueous solution of phenol .. .. 100 c.cm.
Filter and add boric acid, 1 g.
Stand for two hours, add acetone 5 c.cm. Stand for two hours, add resorcin, 10 g. Keep in a dark bottle.

For the dyshidrosiform eruption the feet and hands may be soaked twice daily in a solution of potassium permanganate, 1 in 500 to 1 in 1000, together with nightly applications of Whitfield's ointment. If the latter be applied for too long a period, however, it may itself cause an irritant dermatitis and should then be replaced by an emollient preparation such as cold cream.

True Dyshidrosis.

The above treatment would be disastrous in the case of non-mycotic dyshidrosis. As already stated, this condition runs a limited course and no means of aborting an attack in the early stages are yet known. The methods of treatment applicable to the various stages of eczema should be employed. In the acute vesicular stage simple lotions or watery pastes are best—e.g., lead lotion, calamine lotion, or the following preparation: glycerin, talc, zinc oxide water, āā p. æ. If secondary pustular infection be present it is advisable to open and swab the pustules twice daily with an antiseptic lotion, e.g. :—

Copper sulphate	2
Zinc sulphate	7
Camphor water	300, diluted 1 in 10.

In the early desquamative stage creams and pastes should be employed, e.g. :—

	Ichthyol	♏ 5
	Zinc oxide, olive oil ..	āā 1 oz.
	Anhydrous wool fat	drs. 2
	Lime water	drs. 6
or	Zinc oxide, starch	āā drs. 1½
	Soft paraffin..	to 1 oz.

In the final stages mild keratoplastic pastes may be employed, such as :—

Ichthyol	♏ 5
Liq. pic. carb.	♏ 30
Zinc oxide, starch	āā drs. 1½
Soft paraffin	to 1 oz.

Throughout the treatment it is advisable to keep the hands at rest as much as possible, and there is little doubt that complete rest in bed shortens the duration of an attack. As in eczema generally, soap and water is badly tolerated and the hands may be cleansed only with olive oil or normal saline.

Prevention.

Unfortunately, no dietetic restrictions or treatment with drugs appear at present to serve any useful purpose, and the only preventive treatment consists in mechanical inhibition of the activity of the sweat glands by means of X rays. In some cases this form of treatment has been remarkably successful. For example a boy aged 12, an out-patient attending the West London Hospital, had suffered for three years from frequent attacks of dyshidrosis; he was obese and sweated profusely. The course of X rays advised by Sicoli—namely, three doses of 4 H unfiltered at 15 day intervals—was given by Dr. Carter-Braine at the hospital. The attacks ceased and have not recurred after three years. Bigger dosage with heavy filtration has also been proved effective.

It must be admitted, in fact, that in the present state of knowledge regarding the pathogenesis of true dyshidrosis the only practical method of preventing future attacks is the purely mechanical measure of causing partial atrophy of the sweat glands by X rays.

G. B. Dowling, M.D., M.R.C.P. Lond.,
Dermatologist to the West London Hospital; Assistant Physician to the Skin Department, Guy's Hospital.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

Surg.-Lt. C. G. Rippin is placed on the retd. list.

R. M. B. Lowis to be Surg. Lt.

Proby. Surg. Sub-Lt. W. E. Thomas to be Surg. Sub-Lt.

ROYAL NAVAL VOLUNTEER RESERVE.

Proby. Surg. Lt. C. A. Mather to *Victory* for Haslar Hosp.

Surg. Lt.-Comdr. (D.) A. G. Pridham to *Vivid* for R.N. Barracks.

ROYAL ARMY MEDICAL CORPS.

Lt. A. Guirdham resigns his commn.

R. H. Small is granted a temp. commn. in the rank of Lt.

ARMY RESERVE OF OFFICERS.

Col. G. M. Goldsmith, late R.A.M.C., having attained the age-limit of liability to recall, ceases to belong to the Res. of Off.

TERRITORIAL ARMY.

Lts. W. H. M. Jones, W. L. Lamb, and J. N. Russell to be Capts.

R. S. T. Sandberg (late Offr. Cadet, Lond. Univ. Contgt. Sen. Div., O.T.C.), A. D. Bourne (late Offr. Cadet R.Q.M.S., Lond. Univ. Contgt., Sen. Div., O.T.C.), and F. H. Taylor (late Offr. Cadet, Univ. of Durham Contgt., Sen. Div., O.T.C.) to be Lts.

Medical Prayer Union.—In connexion with the British Medical Association's meeting next week a medical missionary breakfast will be held under the auspices of the Union on Friday, July 24th, at Stewart's Restaurant, Victoria-place, Eastbourne, at 8.30 A.M. The chair will be taken by Dr. W. G. Willoughby, president of the Association, and an address will be given by Dr. A. R. Cook, of Uganda. Those who intend to be present are asked to inform Dr. Victor G. Williams, 6, College-road, Eastbourne.

SPECIAL ARTICLES

THE BACTERIOLOGICAL CONTROL OF MILK-SUPPLIES.

By James McIntosh, M.D. Aberd.,
DIRECTOR OF THE BLAND-SUTTON INSTITUTE OF PATHOLOGY, THE MIDDLESEX HOSPITAL; PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF LONDON;

AND

Lionel E. H. Whitby, *C.V.O.*, *M.C.*, M.D. Camb., M.R.C.P. Lond., D.P.H.,
BACTERIOLOGIST TO THE MIDDLESEX HOSPITAL.

The problem of obtaining an efficient and good milk-supply for an institution such as a hospital involves a consideration of the economic aspect, of the nutritional value, and of the cleanliness and wholesomeness of the milk.

The economic aspect is concerned not only with the question of actual cost, which, for an institution, must be reasonable and therefore tends to prohibit the use of high-grade milk, but also with the matter of keeping qualities which, being intimately bound up with the bacterial content and therefore controllable, has received considerable attention from the large dairy companies.

As to nutritional value there has been much discussion in the press and in Parliament as to the relative values of the different grades of milk, but on the whole the expensive high-grade products are outside the purse of the average hospital; for an institution the problem resolves itself into the purchase of milk of good average nutritional value.

The question of cleanliness and wholesomeness is one that can be partly *safeguarded* by modern methods and without undue expense. It is with this aspect that we have been mainly concerned. We have examined in a routine manner both for the total bacterial content, which largely governs the keeping qualities, and for the presence of pathogenic bacteria, particularly the tubercle bacillus. Our investigations on the Middlesex Hospital milk-supply have extended over some six years. As the result of our experience we feel justified in offering considerable criticism both of the standard technique for determining total bacterial content as well as of the popular "holding" method of pasteurisation, and we would emphasise the necessity for continuous as distinct from intermittent bacteriological control.

Standards of Cleanliness.

It is recognised that a limited number of bacteria are unavoidable contaminants, but large numbers are, with healthy cows, some index of the care and cleanliness in production, handling, transport, and storage. A sample which has a high bacterial content soon after milking shows either that the milking process has been carried out under unhygienic conditions or that the cow, owing to disease, is unfit to contribute milk to the pooled supply of the farm; in older samples, high bacterial content points to faulty storage, whilst a constant low count in an untreated sample indicates care at all the stages from the cow to the consumer. From the point of view of bacteriological control, examinations made should be both quantitative and qualitative, the former for an estimate of wholesomeness, a check on the handling and distribution, and the latter for detecting the presence of pathogenic bacteria. Thus the important features to insist on are: (1) the absence of living tubercle bacilli, (2) the absence of epidemic-producing bacteria, (3) a reasonable bacterial content such as will not impair the keeping qualities.

To meet these requirements three main methods have been advocated:

(*a*) Rigorous and expensive standards for cow, milker, method of milking and transport, with the object of supplying untreated milk with a low initial bacterial content—Certified Milk.

(*b*) Less stringent but still expensive methods for the production of the various forms of Grade A Milk (Grade A, tuberculin tested; Grade A; Grade A, pasteurised).

(*c*) The efficient pasteurisation of milk from reasonably well-conducted farms.

Types of Milk Examined.

GRADE A, T.T. MILK.

The legal standard under the Milk (Special Designations) Order, 1923, is a limit of 200,000 bacteria per c.cm. We have examined a number of samples of the Grade A, T.T. milk as supplied to the hospital, and on one occasion only the bacterial content was above the legal limit (Table I.). On two or three occasions, in the summer months, the supply has been sour before the sealed bottles were opened. It would seem, therefore, that unless a constant analysis is made there is no evidence that Grade A milk is always as pure as the labelled bottle would lead one to believe. The same case can be made against tuberculin-tested samples, for who is to say that a cow may not become tuberculous in the intervals between the tuberculin test.

TABLE I.—*Grade A.*

Admittedly the nutritional value of Grade A milk is high but, in common with Ledingham[1] and the majority of medical men, we are of the opinion that in hospitals, at least, the Grade A milk should be efficiently pasteurised before distribution in the hospital. The inference from this opinion is that the value of Grade A milk is mainly nutritional and that provided a *milk of similar character is obtained* and efficiently pasteurised then there is no advantage at all in using the much more expensive Grade A and Certified products.

ORDINARY MILK.

For the past six years regular quantitative analyses of the churn milk supplied on contract to the Middlesex Hospital have shown that the milk, as supplied, has such a high bacterial content, particularly in the summer months, that the *keeping qualities* are almost negligible (Table II.). Examinations for tubercle bacilli by animal inoculation have from time to time proved positive.

The efficiency of the hospital pasteuriser has been checked by parallel analyses made before and after pasteurisation (Table II.) and these show that the initial high bacterial content can be reduced to a few thousands per c.cm. No tubercle bacilli have been detected in the pasteurised samples. The necessity for keeping a regular watch on the efficiency of a pasteuriser has been evident from time to time.

* Pasteuriser thereafter modified and readjusted.

The Ministry of Health definition of pasteurisation is "the retention of milk at a temperature of not less than 145°F. and not more than 150° F. for at least half an hour and then immediate cooling to a temperature of not more than 55° F., the milk being heated once only and not otherwise treated by heat." This is a description of the "holding" method as practised by most of the large dairy companies. The hospital pasteuriser was worked on the "flash" principle in which the milk was rapidly heated to 160°–165° F. in a space of about four minutes and then quickly cooled to 40°–45° F. by flowing over water- and brine-cooled pipes. We have been unable to detect any alteration in taste or character of the milk so pasteurised, and in view of our bacteriological findings on milk pasteurised by the "holding" method (Tables III. and IV.) we submit that the "flash" principle is the better method. We do not condemn the "holding" method, but we consider it is very liable to fail on occasions which are not easy definitely to foresee for reasons which we shall presently state. It is quite evident that if a milk of good nutritive value is obtained pasteurisation efficiently carried out provides a method of rendering the milk clean and wholesome.

PASTEURISED MILK.

The samples of this type of milk have been mainly that sold to the hospital as "pasteurised milk" (Table III.), that is, milk which under the Milk (Special Designations) Order should not contain more than 100,000 organisms per c.cm. During the warm months, May–September, these samples have often had a bacterial content of several millions.

This fact was further brought home to us by the finding of many millions of viable organisms per cubic centimetre in some samples of "pasteurised milk" sent to us for analysis by the Medical Officer of Health of Islington in the summer of 1928 (Table IV.). It may be said without prejudice that these samples came from a retail shop of a large firm of dairymen whose pasteurising plant is the most up to date in the world; a firm who make every effort to supply the public with clean and wholeso milk and who employ a staff of highly trained bacteriologists and chemists to assist them in so doing. The result of our analysis came as a bombsh to the dairy company, but they gave us every oppo tunity to confirm our findings with other samp both from their retail depôts and from th pasteurising centres. This we were able to (Table IV.), though the bacteriologists of the compa were, with parallel samples, getting results whic were well within the legal limit. There was naturall considerable discussion, entirely amicable, to accou for the discrepancies in the parallel examination which resulted in considerable instruction to ourselve and them. The discrepancies were traced to difference in the technique of the examination, a the high bacterial counts were found to be due mai to heat-resisting bacteria.

Technique of Examination.

Our usual technique for the hospital milk analys has been the making of ten-fold dilutions of the sample in sterile saline, ensuring proper mixing by shaking the dilutions in glass-stoppered bottles. The dilutions have been plated in ordinary agar and in litmus-lactose agar, both made from meat broth. On the other hand, the Ministry of Health circular, though recommending the making of dilutions in essentially the same manner, instructs the bacteriologists to plate out in agar medium made from peptone water and lemco. The formulæ of the three media are appended for comparison:—

	Ordinary agar.	Litmus-lactose agar.	M. of H. agar.
Water	—	—	1000 c.cm.
Meat extract ..	1000 c.cm.	1000 c.cm.	—
Peptone	10 g.	10 g.	3 g.
Sodium chloride ..	5 g.	5 g.	—
Lemco	—	—	3 g.
Lactose	—	10 g.	—
Agar	20 gr.	20 g.	15 gr.

It was very evident that the discrepancies between our results and those of the dairy company were due to the richness of our medium as compared with the poor nutrient value of that recommended by the Ministry of Health. Table V. shows the comparative results of two samples using the three media. The results, which are typical examples of several analyses, show firstly that our two media both detect more viable bacteria than the medium of the Ministry of Health and, secondly, that on some occasions the litmus-lactose agar is definitely superior to ordinary agar. The significance of this we shall discuss later.

The moral of the results is clear. That though it is highly desirable that the Ministry of Health should lay down a standard technique in order that results may be comparable, it is wrong that that echnique should involve the use of a medium of so poor a quality that it does not give any indication f the content of *viable* bacteria though the content limited by law to 100,000 per c.cm.

TABLE V.—*Pasteurised Milk.*

Sample.	Bacteria per c.cm. using various media.		
	Ordinary agar.	Litmus-lactose agar.	M. of H. agar.
1	20,000,000	24,000,000	5,000
2	8,000,000	36,000,000*	76,000

* Excess growth on litmus-lactose-agar due to thermoduric treptococcus.

NIFICANCE OF ORGANISMS GROWN ON RICHER MEDIA.

On the richer media we obtained heavier growths f all organisms that appeared on Ministry of Health edium. In addition, there were two organisms which we were unable to detect on Ministry of Health edium. It may be said with confidence that the dditional organisms did not have the slightest athogenic significance but, on the other hand, one any rate was of some economic importance for it as a short-chained streptococcus capable of rmenting lactose.

Briefly the organisms were of two main types: (1) *Bacillus.*—A thin Gram-positive non-sporing acillus belonging to the group known as thermoiles. It was capable of slow growth in agar at C. and appeared as minute pin-point colonies etable with a hand-lens. These colonies, if cultivated on to agar slopes, grew profusely when ncubated in a water-bath at 56° C. These were definite thermophiles, as described by Ayres and Johnson[3] the optimum temperature for which is said to be 47° C.–63° C., and were detectable in both agar and litmus-lactose agar. They had no fermentative power, they were found in the hot summer months and have been fairly thoroughly investigated in America. If once implanted into a pasteurising plant of the "holding" type they are liable to be a chronic nuisance.

(2) *Streptococcus.*—A short-chained streptococcus, often diplococcal, appearing as very small fusiform colonies particularly in litmus-lactose agar and easily detectable on account of the small surrounding zone of fermentation. This organism was not thermophilic but was definitely thermoduric, for it resisted immersion in a water-bath at 60° C. for one hour. This organism was also found in the summer months and successful cultivation was very definitely favoured by the presence of lactose in the medium. It is fair to infer that the lactose of milk favours the multiplication of this organism and that the Ministry of Health medium fails to detect the fact.

Discussion.

We have furnished sufficient evidence to show that milk pasteurised in large quantity by the "holding" method often contains more viable bacteria than the Ministry of Health will allow, but that the determination of this fact is not possible by using the methods advocated by the same authority. We strongly advocate that richer medium should be used for routine analyses. Our experience (e.g., Table I.) shows that provided the sample of milk is clean, the richer medium still gives results within the present legal standards. The dairy companies themselves are aware of the difficulties of dealing with thermophilic and thermoduric organisms and they do their utmost to eliminate the trouble, yet their "official" bacteriological examinations show that their methods of pasteurisation are sound. It is the dairy companies who have discovered that trouble with thermophilic bacteria is seasonal; that "foaming" and "pocketing" of the milk during passage through the numerous pipes favour the multiplication of thermophiles; that the use of a pasteurising plant for a consecutive period of *more than four hours* causes a *great increase* in thermophiles; that a breakdown in the plant causing delay or prolongation of the time of pasteurisation ("overholding") has the same effect. Thermoduric and thermophilic bacteria are very liable to be implanted in a pasteuriser when milk that has been previously heated is mixed with unpasteurised milk and the whole mixture then pasteurised—a process known as "seeding." The trouble would appear to be not so much with the dairy companies who are aware of a good many of the troubles that may be caused in the plant, but with the unscrupulous farmer, who to cover his dirty methods, heats the milk before sending it to be pooled with the rest of the dairy company's supply. This is the probable cause of the results given by two analyses which the dairy company asked us to make with our media—an analysis of the raw milk and then of the same milk as it appeared sealed and bottled at the other end of the pasteurising plant. The samples had more viable bacteria after pasteurisation than before (Table VI.).

TABLE VI.—*Milk from Pasteurising Centre of Dairy Company.*

Sample.	Bacteria per c.cm.	
	Raw milk.	Pasteurised milk.
1	632,000,000	1,088,000,000
2	7,000,000	24,000,000

There can be little doubt that large scale pasteurisation by the "holding" method does not always achieve the reduction of bacterial content which the Ministry of Health desire. And as it is probable that the blame for this failure does not rest with the dairy companies, there is provided another incentive for a closer control and supervision of the farmer with a view to stimulating him to attain a high standard of cleanliness and quality. Pasteurisation as generally used at present is not the last word in the provision of clean and wholesome milk.

SUMMARY.

(1) Bacteriological control of milk-supplies is an adequate control of purity if the analysis is properly performed. Control must be continuous and not intermittent. (2) Only by the use of media capable of growing delicate micro-organisms can a proper bacteriological control of milk be made. (3) The present method of analysis advocated by the Ministry of Health does not detect all viable bacteria. (4) Pasteurisation by the "holding" method is liable to fail with regard to killing thermophilic and thermoduric bacteria. (5) The "flash" method of pasteurisation

is less open to the above objection and at the temperature used (160°–165° F.) is not only efficient but produced no detrimental change in the milk. (6) Comments on the probable origin and the significance of the more important thermophilic and thermoduric bacteria.

MEDICINE AND THE LAW.

The End of the Jury of Matrons.

PARLIAMENT has at last abolished the jury of matrons as a part of our criminal law. The use of such a jury, to decide whether a woman convicted of a capital offence is pregnant or not, is of great antiquity, dating from times when medical science was non-existent or at any rate not commonly available. Had the occasions for its use been of greater frequency or publicity, its existence could hardly have been tolerated so long. Thirty years ago, the late Sir Harry Poland expressed the general view that the jury of matrons should be abolished, "but who," he added, "dare propose such an interference with the rights of women?" The answer is that the initiative has come from a woman Member of Parliament, representing a large proportion of women electors.

The Sentence of Death (Expectant Mothers) Act, which has now effected this reform, is strangely named, for it abolishes the death sentence where an expectant mother is convicted, penal servitude for life being substituted. It has long been the law that a pregnant woman should not be executed; the new statute saves her from a meaningless sentence. The change in the method of deciding the question of pregnancy is a more substantial matter. Formerly, the judge directed the immediate impanelling of a jury of twelve matrons or "discreet women" to answer the question. They were chosen *de mulieribus circumstantibus*, and, to prevent evasion of the duty, he would order the doors of the court to be shut. Unseemly scenes have been witnessed when women of a former generation, unused to any kind of jury service, scrambled to escape. It used to be said, indeed, that the attendance of feminine spectators at the Old Bailey diminished for a long time after such an incident at the trial of Katherine Webster in 1879. This ancient method of ascertaining pregnancy was far from infallible. In 1847, for instance, Mary Ann Hunt was convicted of murder in London. At the next session a jury of matrons was impanelled to try whether she was "with child of a quick child"; the matrons searched and examined and gave their verdict in the negative. She was left for execution, but the surgeon at Newgate reported to the Home Secretary to the contrary. The latter, showing, as Sir Harry Poland used to say, wisdom not less than that of Solomon, declared that a few months would settle the question. A few months later the child was born.

The new method of deciding the question of pregnancy is remarkable. Obsessed with the preservation of the ancient forms of British justice, Parliament has now entrusted the decision to the trial jury, who need not be resworn for the purpose. If there is no trial jury, or if the trial jury has disagreed on the question, a new jury is to be sworn specially for the purpose. Finally the woman has a right of appeal from the jury's verdict that she is not pregnant. All this is cumbersome and otiose. Is it really necessary to detain twelve jurors from their everyday work to undertake this investigation? Need the time of the Court of Criminal Appeal be occupied with such appeals? The evidence is bound to be medical in character; it could perfectly well be obtained directly by the judge from medical practitioners. It does not seem to have occurred to Parliament or the Home Office that the Irish precedent was preferable. More than fifty years ago the Juries Procedure (Ireland) Act provided that "the court shall direct that one or more medical men be sworn to inquire whether she be with child of a quick child"; if, after due inquiry, he or they report in the affirmative, "the court must stay execution till the woman is delivered of the child or until it is no longer possible in the course of nature that she shall be so delivered." Common sense might have suggested the application of some such machinery for the purposes of the new Act in England.

Cancer and Chiropractic Treatment.

An inquest was recently held at Bath upon the death of a retired Indian Army officer, aged 58, who had suffered from cancer of the prostate. Dr. Alister Sutherland gave evidence that the state of cancer was inoperable when first seen and that life could no have been prolonged for more than six months o a year. The deceased underwent chiropractic treatment in spite of Dr. Sutherland's warning that an severe manipulation of the spine would be dangerous he became rapidly and progressively worse after th treatment. An X ray photograph taken at an earli stage showed no evidence of spinal fracture or disease another taken after the chiropractic treatmen showed definite evidence of a fracture of the vertebr A woman chiropractor who had given the treatme stated that she had graduated in America in 1 and had practised in spinal work. She examin the deceased and picked out the vertebræ w were slightly out of alignment; these, she said, b pressing on the nerves, caused pain. It was he duty to get rid of this pressure and so relieve the pai It was not a severe treatment. Asked by the corone to describe it, she said it consisted of a little shor thrust; it was not a long manipulation. The deceased told Dr. Sutherland that the chiropractic treatment had relieved a certain number of his pains, and that as the doctors had no alternative to offer, he wa going on with it. He had told the chiropractor that he had been in the hands of the doctors and was getting steadily worse. He visited her three times she stated, and he said he was improved each time. A verdict was returned of death from cancer of the prostate gland accelerated by a fracture of the spine

---

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

THE GERMAN AERZTETAG.

THE Aerztevereins-Bund and the Hartmannbund, which are two distinct but closely associated bodies, have just held a joint annual meeting in Cologne. The importance of this year's meeting was emphasised by the fact that the Government was represented by the Minister of the Interior, Dr. Wirth. In his address he pointed out that owing to the financial stress it had been necessary to diminish the sum allocated in the national budget for social insurance.

This was unfortunately bound to affect the medical profession. The first subject of discussion at the meeting was the reform of the laws governing medical practice. The regulations relating to medical practice have since 1867 been included in the laws concerned with trades (Gewerbeordnung), and this connexion has been greatly resented by the profession. The discussion was opened by a lawyer, Prof. Ebermayer, formerly director of public prosecutions, who said the medical man was not in any sense a tradesman, but was an officer of public health. The conditions of medical practice differ in all respects from those of a trade. One of the provisions needing adjustment was that whereby a medical qualification could be withdrawn for good only if obtained in a fraudulent way and could be withdrawn temporarily only if a medical man had been found guilty of a crime and punished with a temporary loss of civic rights. The chairman, Dr. Stauder of Nürnberg, spoke on the future organisation of the profession. He looked forward to the time when the medical chambers, which are State organisations with disciplinary powers, would be brought into closer connexion with the voluntary organisations of the profession such as the Aerzteverein and the Hartmannbund. He protested against the last emergency ordinance whereby the profession was fettered in an intolerable way in its association with health insurance work and whereby the younger generation of medical men was excluded from that work for a considerable time after qualification. Other items discussed included the influence of unemployment on the public health in general, the reform of the insurance laws, and the question of post-graduate study. The meeting considered the use of asphyxiating substances and of bacteria in a future war and the protection of the population against such attacks. The Government was invited to take steps towards convening an international congress to stop the manufacture of such war materials.

DEATH OF PROF. MINKOWSKI.

Prof. Minkowski, one of the most celebrated physicians and pathologists of Germany, died in Wiesbaden on June 16th. Born in Kowno (Lithuania), in 1858, he became privat-docent in Königsberg at the age of 27 and six years later extraordinary professor in Strassburg. In 1900 he was appointed chief physician to the Cologne General Hospital and professor in the Academy of Medicine of that city, which has now become a faculty of the local university. Later he was appointed to the chair of medicine at Greifswald and then was invited to Breslau to succeed the late Prof. Strümpell. Prof. Minkowski's work was of fundamental importance, especially in connexion with diabetes. In 1884 he detected the presence of oxybutyric acid in the urine of diabetic patients, and formed the view that diabetic coma was due to an acid intoxication of the blood. He discovered later the part played by the pancreas in diabetes. Finding that after removing the pancreas of dogs sugar was present in their urine, he came to the conclusion that the pancreas must contain the substance necessary for the decomposition of carbohydrates and that its absence must thus lead to the excretion of sugar. His experiments thus formed the basis of the complex work on carbohydrate metabolism which eventually led to the discovery of insulin. Prof. Minkowski also worked on the pathology of gout, liver diseases, and diseases of the respiratory organs. During the war he turned his attention to the study of the morbid condition caused by gas poisoning. He had a large practice as a consultant in Breslau until he retired in 1926 to spend the rest of his life in Wiesbaden.

AN ACTION FOR UNFAIR COMPETITION.

Dr. Neustätter, the head of the anti-quackery department of the Dresden Exhibition of Hygiene held this summer, allowed the exhibition of a poster showing a man, who had run astray by following sign-posts leading to certain quack remedies, eventually finding his way back on to the road of scientific medicine. The producers of certain compounds mentioned in the picture brought an action against Dr. Neustätter before a court in Dresden for unfair competition and Dr. Neustätter was ordered to pay damages to the plaintiffs. In the judgment the court stated that Dr. Neustätter's picture was designed to induce patients to abstain from using the compounds mentioned instead of consulting qualified medical men and that the exhibition of the poster must thus be regarded as unfair competition. The Berlin Medical Society lately discussed the judgment. The chairman, Prof. Goldscheider, recalled the fact that 60 years ago the society had successfully petitioned for the abolition of the anti-quackery laws in the belief that the public was reasonable enough to decline to use quack medicines without legal restrictions being required. Its members had, however, been greatly disappointed. The Dresden judgment had proved this view to be untenable. The society finally adopted a motion that the exhibition of the poster was not inspired by commercial motives but by the wish to serve the public health. By wrongly interpreting the purposes of the exhibit the Dresden court had, it was felt, struck a blow against the honour of the profession. It was the duty of the profession to fight an unscientific outlook and attempts in this direction could not be regarded as unfair competition.

THE LÜBECK TRIAL.

The trial of the Lübeck medical men on a charge of manslaughter by negligence in the application of the Calmette treatment will take place in October. This is the biggest trial on record in Lübeck, since the public prosecutor is backed up by all the 250 parents of the children who died or were damaged in health after receiving treatment in the spring of 1930. A large number of witnesses will be summoned by the defence and by the prosecution, including Prof. Calmette, who has declared his readiness to appear before the court.

AN INTERESTING LAW-SUIT.

The question whether a medical man is entitled to charge for attendance on his wife was lately decided by the High Court in Leipzig. The wife of a medical man had been run down by a motor-car and severely injured. She was attended by her husband and in due course sent the owner of the car a note of her expenses, including accounts for medical attendance. The owner of the car declined to pay the doctor's bill, because he considered him obliged to attend members of his family free of charge. The High Court found against this view. In the judgment it was stated that one who has injured the health of a person cannot decline his financial responsibility under the pretext that the injured person had had no expenses because she was attended by her husband, who must be supposed to attend her free of charge. Such attendance not only requires time which the medical man might have spent on other patients, but also the use of medical instruments and of dressing materials. The defendant had thus to pay the sum charged by the medical man.

A NEW HOSPITAL IN BERLIN.

A new hospital, called the Martin Luther Hospital, was recently opened in Berlin. It has been erected information as to cases sent to the in-patient or out-patient departments of hospitals. But the criticism was based on a misunderstanding. The capitation fee to insurance practitioners included a payment for certain records to be kept by them. Until recently these records were two in number. Instead of requiring a daily record of visits and attendances for insured persons, as was kept by all English practitioners, the Department, after consultation with representatives of the British Medical Association, and with their concurrence, resolved to introduce a scheme whereby insurance practitioners would be given an opportunity of helping in clinical and administrative investigations. Their aim was to link up the insurance practitioner with research. The obligation to supply information in connexion with these investigations had taken the place of the obligation to send in annual summary cards. The insurance practitioners' part was to supply on a form a report on patients for whom they sought in-patient or out-patient treatment. He was satisfied that a doctor, even in a busy industrial area with a panel of 1500 persons, would not, on the average, require to send to the Department two reports a week. Surely it would be agreed that the insurance practitioners' part in this valuable investigation did not involve a serious encroachment on his time. Moreover, it was work undertaken as part of his agreement, and he was being paid for it.

Morbidity statistics had been collected for almost a year, and he said they hoped to publish a special report which would discuss more fully than had already been done some of the conclusions that might be drawn from the statistics. This would be the first report to be issued in this country dealing with sickness among the insured population. They had also nearly completed the first of what they hoped would be a series of investigations into the sickness experience of particular occupational groups of workers. Among other problems which had been already thrown up by the morbidity statistics he might cite the following: Why should a married woman require six days longer on an average than a single woman to recover from an illness? Why should the average duration of incapacity in the more isolated areas of the country be very much longer than it is in the more populous centres? What is the reason why, in one particular case of a fairly large panel, there should be a certification rate of 25 per cent. of the number of the panel during six months?

Mr. Jeffrey added that the increasing burden on women's funds had given rise to the greatest anxiety.

PUBLIC HEALTH SERVICES

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are 1930 statistics of one county and three county boroughs:—

Name of district and estimated mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Infant and neonatal mortality.	Young child (1–5 yr.) mortality.	Maternal mortality in childbirth.
Wiltshire .. (299,933)	15·2	11·3	0·61	1·66	0·9	2·6	51/—	—	3·2
Plymouth .. (199,000)	15·9	11·8	1·00	1·59	2·1	1·8	61/27	35	7·6
Sunderland.. (184,000)	23·1	13·5	1·36	1·14	2·7	2·0	78/34	41	3·8
Walsall .. (100,100)	20·6	11·2	1·11	1·14	1·8	2·1	69/35	20	5·3

Registered stillbirths per 100 live births:—Wiltshire 3·6, Plymouth, 5·3, Sunderland 4·0, Walsall, 3·3.

Wiltshire.

Dr. Claude E. Tangye states that the out-relief districts under the boards of guardians have been reduced in number by two. Formerly many of the applicants for relief called at the relieving officers' homes and there was one pay station at Swindon. Now payments of relief are made in the applicants' homes. The public assistance institutions for the chronic sick number 13, at three of which accommodation is provided for mental defectives, and at one of which there are wards for difficult male cases under male attendants. The services of consultants can be obtained both for institutional and home-treated cases. The hospital provision has been very fully used during the year and there is no serious shortage of general hospital beds apart from the Swindon area. The Pewsey poor-law institution is to form the nucleus of a mental deficiency colony with accommodation, ultimately, for 600. Notice has been received from outside authorities that the cases accommodated outside the county can be no longer retained. At present there are 84 males and 108 females in outside institutions. Since the Housing (Rural Workers) Act came into operation in January, 1927, 181 applications for grants or loans have been received by the county council, 31 of which were made during 1930. At the end of 1930, £6452 had been paid in respect of 77 houses, and work on 25 other houses had been begun. The Housing Act of 1930 puts new duties on the county council, and every rural district council must furnish information on overcrowding and unsatisfactory conditions, and the steps being tak to ascertain them. Dr. Tangye regrets that so far very few rural district councils have furnished this information. The Act enables the county council to make contributions to rural district councils for housing the agricultural population.

Outside Swindon the urban areas in the county retain their character of country towns and social conditions, and occupations are favourable to health. The district nursing associations cover the county area almost completely, and the county council, under the new Local Government Act, contribute towards midwifery, maternity nursing, and health visiting carried out by these associations. The handy woman has practically disappeared and almost all confinements are attended by midwives, either as such, or as maternity nurses. The standard of antenatal work carried out by midwives has shown a decided improvement, and the county council have approved a scheme for antenatal supervision by the family doctor, who is to attend the confinement. There are five maternity homes used by the county council, the total admissions to which were 741. The net cost to the county council for the 253 cases sent in by them was £2 2*s*. 6*d*. per patient.

Hitherto the inspection of dairy herds has been confined to the follow-up of tuberculous milk samples complained of by outside authorities, but on Oct. 1st the part-time veterinary inspector, Mr. S. V. Galledge, was appointed on a full-time basis, and Dr. Tangye points out that systematic inspection of all dairy cows must be the eventual aim in this great dairy-farming county. An outbreak of trichiniasis associated with the consumption of uncooked pork in potted meat from a meat factory accounted for seven cases of acute illness. The patients all recovered, though some were gravely ill. Two cases of fatal septic poisoning occurred at a dairy farm; both men were milkers. The first patient infected the teats of two cows and the second patient received the infection by milking these cows. The organism was a hæmolytic streptococcus. No harm resulted from the use of the milk, for it was sterilised at a factory.

Dr. Tangye wishes to see hospital treatment provided for measles and whooping-cough, with their high pneumonia fatality, rather than for the comparatively mild scarlet fever.

Plymouth.

Dr. A. T. Nankivell's report shows that Plymouth has in hand a big scheme of hospital reorganisation. There are three voluntary general hospitals with 240, 60, and 50 beds, respectively, and an eye infirmary with 28 beds. One of these general hospitals has recently absorbed the Eye, Nose and Throat Hospital and a scheme is in hand for the amalgamation of the three general hospitals, which will render classification of patients possible and, incidentally, facilitate negotiations between the voluntary and the municipal hospitals. Dr. Nankivell points out that there is no hard-and-fast line now between voluntary and municipal hospitals, and he hopes that the vague phrase "the Voluntary System," will not prove a formidable barrier in these negotiations for complete coöperation. In April, 1930, the municipality took over the three workhouses of the three towns. These were mixed workhouses of the old type. One of them—the Greenbank poor-law institution—has been transferred to the health committee and is to be converted into an up-to-date hospital. A medical superintendent and a complete visiting staff, paid by fees for services rendered (except in the case of the physicians), has been appointed. Before April last Greenbank was a workhouse holding 200 sick and infirm and a like number of able-bodied and lunatics; also some tramps, test workers, and all the mixture of the old workhouse. The able-bodied were transferred to the Devonport institution under the public assistance committee. The lunatics were sent either to Devonport or to the asylum, the tramps to the Stonehouse workhouse, and the children were passed over to the maternity and child welfare committee or the education committee; and during April all the poor-law sick from Stonehouse and Devonport were taken to this new city hospital. The buildings of the hospital were in a bad state of repair, and at the end of 1930 renovation was about half finished and accommodation for 550 patients available. Dr. Nankivell gives a graphic description of the want of equipment, human and otherwise, and of the wastage under the old régime. The central heating, at a cost of £4760 per annum, was doing very little work and most of the steam pipes leaked. During the last half of 1930 food cost £700 per annum less and the patients were better fed than ever before. The medical superintendent, Dr. Ivor Lewis, says there are now 23 maternity beds, and that it is hoped to develop antenatal work so as to form a consultative clinic for the practitioners and the maternity and child welfare officers. For this purpose out-patient accommodation is required. Medical out-relief under the old poor-law, which was working well, has come under the control of the health department. The principal change made is that the nine part-time practitioners are being asked to give prescriptions as under the National Health Insurance Act. The former dispensary has been closed and the new scheme has worked well since September.

Other municipal hospital developments are: Swilly Hospital, at present used mainly for tuberculosis, has been greatly extended at a cost of £47,000 and will be open during the current year as the isolation hospital; Mountgold Hospital, at present used for scarlet fever and diphtheria, will accommodate intermediate and advanced cases of pulmonary tuberculosis in men and women; on the high ground adjacent to Mountgold Hospital an orthopædic hospital is to be built to accommodate 120 patients; while Udal Torre Sanatorium, at Yelverton, an unsuitable building, is to be closed.

Dr. Nankivell complains of the slow progress made with slum clearance. Five years ago three slum areas were scheduled, and the city council readily agreed to their reconstruction. These areas should have been cleared three years ago, but nothing except some reconditioning has been done. There are other insanitary areas which need to be dealt with. During the next five years 2232 new houses should be built, and of these 1000 should be built as soon as possible. The lack of suitable sites retards progress in housing, and Dr. Nankivell thinks lofty blocks of modern flats on some of the insanitary areas in Stonehouse might be a desirable way of meeting the difficulty.

Sunderland.

Dr. A.S. Hebblethwaite states that on April 1st, 1930, Highfield poor-law institution was handed over to the public assistance committee, and that it has since been arranged that on April 1st, 1931, the medical, surgical, maternity, tuberculosis, and isolation wards and the nurses' home will be constituted a municipal hospital under the health committee. No changes have been made in the poor-law medical out-relief districts since their transference.

There are about 30,000 houses in the borough and 3600 people waiting for corporation houses. It is pointed out that the number on this list is not necessarily proof of great shortage, many applications being from persons who merely desire a change. The houses built during the year numbered 756, as compared with 410 in 1929. An increasing number of houses is being dealt with under Section 3 of the Act of 1925 and Section 17 of the Act of 1930. In 1928, 126 of these were renovated by the owner and 28 by the municipality in his default. In 1929 the figures were 317 and 55, and in 1930 647 and 44. The owners therefore show a decidedly increasing inclination to carry out the repairs themselves. The five-year housing programme puts forward ten clearance areas, involving 653 dwelling-houses and 6646 persons. The municipality expects to build 3000 new houses, of which 1000 will be needed to accommodate the population of the ten clearance areas and of additional individual houses to be demolished. The tuberculosis death-rate was exceptional in 1930 in that there were more deaths from non-pulmonary than from pulmonary tuberculosis, and Dr. Hebblethwaite points out that during the last five years there has been a definite decrease in tuberculosis of the lungs, but a definite increase in tuberculosis of the glands, bones, and joints. Dr. Eustace Thorp, who is in charge of the isolation hospital, expresses the opinion that the standard of the State examinations for nurses is far too high and covers too wide a scope. The long distances which nurses have to travel for their oral examinations is another matter requiring remedy.

Dr. Hebblethwaite advocates that general practitioners should have the use of the municipal antenatal clinics and staff at special sessions in order that the antenatal examination and the confinement may be conducted by the same person.

Walsall.

Dr. James A. M. Clark reports that the Manor Hospital and Beacon Lodge (poor-law), being a combined institution, has been placed under the control of the public assistance committee. The hospital contains 300 beds and the medical officer in charge reports that the work greatly increased during the year. For example, surgical operations numbered 85 in 1927, 369 in 1929, and 819 in 1930. The wards are now quite full and extensions are necessary.

The shortage in hospital beds in the borough appears to be general. The new isolation hospital, opened in April, provides only 34 beds. A slight outbreak of diphtheria in the second quarter was sufficient to show the inadequacy, and at the present time proposals for an additional ward block of 24 beds and a block for tuberculosis are before the council. The new maternity hospital, opened in July, 1929, with 11 beds, has proved so popular that many applications had to be refused. Since this hospital was opened antenatal work at the clinics has shown a great increase.

There is a considerable amount of overcrowding, and the corporation propose to build 4000 houses during the next five years, besides houses for rehousing tenants from clearance areas. There are about 2000 small houses built about 60 to 100 years ago, many of which show extensive deterioration. One unhealthy area containing 177 houses, occupied by 935 persons, was represented at the end of the year, and inspections are proceeding with a view to the representation of other areas. About a quarter of the houses are supplied by outside standpipes, serving from two up to 12 houses. Of 16,956 water-closets, 5817 have no flushing cistern and have to be flushed from a bucket or other receptacle. These are being dealt with under Section 36 of the Public Health Act, 1875. By-laws for houses let in lodgings were approved in June and the Walsall Act of 1930 prohibits any tent, van, shed, &c., for human habitation to be placed on any site within the borough without the previous approval of the corporation.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 4TH, 1931.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 56; scarlet fever, 1442; diphtheria, 893; enteric fever, 63; pneumonia, 540; puerperal fever, 51; puerperal pyrexia, 100; cerebro-spinal fever, 39; acute poliomyelitis, 4; acute polio-encephalitis, 1; encephalitis lethargica, 24; dysentery, 13; and ophthalmia neonatorum, 107. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on July 7th–8th was as follows:—Small-pox, 97 under treatment, 1 under observation (last week 124 and 1 respectively); scarlet fever, 1111; diphtheria, 1433; enteric fever, 15; measles, 143; whooping-cough, 449; puerperal fever, 35 (plus 10 babies); encephalitis lethargica, 208; poliomyelitis, 2; "other diseases," 141. At St. Margaret's Hospital there were 11 babies (plus 3 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was 1 (0) death from small-pox, 3 (0) from enteric fever, 16 (0) from measles, 3 (1) from scarlet fever, 21 (4) from whooping-cough, 23 (3) from diphtheria, 31 (7) from diarrhœa and enteritis under two years, and 19 (1) from influenza. The figures in parenthesis are those for London itself.

Three deaths from meningococcal meningitis were reported from London, all in children below five years of age. Three deaths from measles were notified in Leeds, while in Liverpool there were five deaths from whooping-cough, five from diphtheria, and three from diarrhœa and enteritis under two years.

The number of stillbirths notified during the week was 283 (corresponding to a rate of 42 per thousand births), including 46 in London.

DEATH CLASSIFIED TO SMALL-POX.

THE death from small-pox was assigned to Burton-upon-Trent. Dr. J. M. Cowie, the medical officer of health, kindly gives us the following particulars:—"The death certificate was signed as due to 'Variola.' The age of the patient was 75 years. He was probably vaccinated in infancy, but it was impossible to identify with certainty any vaccination marks. The case was a severe one, being of a confluent or semi-confluent character."

OBITUARY

SIR CHARLES HENRY BEDFORD, M.D., D.Sc., LL.D. Edin., I.M.S.

Lieut.-Colonel Sir Charles Bedford, who died on July 8th after a short illness, was the son of Dr. F. W. Bedford, headmaster of George Heriot's Hospital, Edinburgh. He wrote a biography of his father, and a history of the hospital, later advancing its interests in every way he could. A student of Edinburgh University, he graduated in medicine in 1887, in science in 1889, and after a couple of years in general practice joined the Indian Medical Service in 1889, He became professor of chemistry at Lahore and Calcutta, wrote "A Clinical Handbook of Urine Analysis" and a "Practical Chemistry" (their second editions being translated into French, Italian, and German), and became director of the Central Excise Laboratory for India and scientific adviser to the Government of India. He showed the Government that their standards for the taxation of alcoholic liquors were mistaken, recalculated the tables of alcoholic strength and specific gravities, and is said to have saved the revenue a million a year; he also edited for a time the *Indian Medical Gazette.* On retiring in 1911 he received a knighthood. The honorary degree of Doctor of Laws was conferred on him at St. Andrews in 1913, at Edinburgh in 1923, and at Oxford in 1924. During the war he acted as a regional chief commissioner of medical services; he was the first general manager of the Association of British Chemical Manufacturers, and hon. adviser to the Secretary of State for the Colonies on power and industrial alcohol. Later he did a great deal to encourage the foundation of the chair of Spanish studies at Oxford, and was director of the Anglo-Spanish and Spanish-American Institute of Lond He was a Knight Grand Cross of the Order of Ci Merit. Sir Charles Bedford was twice married, leaves no children.

ARTHUR MUSSEN, M.D. Q.U.I.

WE regret to announce the death of Dr. Arthur Mussen, at Templepatrick, in Northern Ireland, on July 3rd. Born at Hillhall, Lisburn, in 1842, he received his medical training in the Queen's College, Belfast, and graduated M.D. of the old Queen's University of Ireland in 1863. He also qualified as M.R.C.S.Eng., and was a licentiate of the Faculty of Physicians and Surgeons of Glasgow. He was one of the last surviving doctors in Ireland to have served a term of apprenticeship with a medical man in practice during his collegiate career. In 1865 he was appointed medical officer of the Glenavy dispensary district, and in that capacity discharged his duties with a faithfulness which gained for him the affection of the countryside. For 51 years he held the post of coroner for South Antrim, and was a Justice of the Peace for County Antrim. Dr. Mussen was prominently identified with the Orange Order, and for 57 years was District Master.

DAVID SOMERVILLE DOUGHTY, M.D. Edin.

Dr. Doughty, who died at Dalston, on July 10th, was born at Thornhill, Dumfries, in 1863, educated at Hutton Hall in the same county, and became in due course a medical student at the University of Edinburgh. After graduating in 1886, he began his medical career as house surgeon to the Dumfries Infirmary, spent a year as an assistant in London, then practised for another year at Hesket Newmarket, in Cumberland. He eventually bought Sir Norman Walker's practice at Dalston, to which he was to devote the rest of his life. He retired from active work only a few weeks ago, owing to failing health. "Of Dr. Doughty, as a man and physician, it is difficult to speak too highly," writes a colleague. "He was the type of man eulogised by the Roman poet of old—'Integer vitæ scelerisque purus.' With a keen interest in his profession, and an abundant store of human sympathy, he was one of the finest specimens of the old-fashioned country doctor one could wish to meet. He had many and varied interests. He was not only a popular doctor; he was a keen follower of hounds, an ardent fisherman, and a first-class game shot. There was no project set on foot calculated to promote the happiness of his neighbours which had not his whole-hearted support. Amongst his other activities he was for many years chairman of the local panel committee of the National Insurance. The meetings of this body he conducted with rare acumen, while his genial good humour soon smoothed down any asperity arising in the course of the discussions."

Dr. Doughty was shortly to be presented with an illuminated address and a substantial testimonial from the people he had served for 42 years.

CORRESPONDENCE

RECOVERY FROM STREPTOCOCCAL SEPTICÆMIA.

To the Editor of THE LANCET.

SIR,—In their interesting report of a case in your last issue (p. 72) Dr. A. H. G. Burton and Dr. A. R. Balmain make certain references to a paper by myself and Dr. R. E. Smith (Guy's Hospital Reports, Jan., 1931) which, to give our findings their due, require expansion and explanation.

1. They state that out of 21 cases described by us only six recovered. They do not mention that these constituted a more serious group, including complicated cases (five of them already the victims of chronic disease) from hospital records, and that the parallel series from private practice showed a recovery-rate of six out of eight traced cases. In other words, there were 12 recoveries out of 29 cases in the whole series reported by us.

2. They state that we regard diarrhœa, albuminuria with red cells, rapidly progressive anæmia, and the smooth red desquamating tongue as diagnostic of a streptococcal infection with an hæmolytic strain, but that these symptoms were lacking in their case. We believe that this is a valuable diagnostic syndrome, but we have not suggested that it is present in every case or with every strain. They also emphasise the absence of rigor in their case. This symptom, so commonly regarded as of outstanding diagnostic importance in septicæmic states, was rare in our hospital series.

3. Although our results with serum treatment were, on a critical analysis, disappointing, we do not altogether condemn the method. Furthermore, we make a special point of suggesting the trial of various brands of serum, which Drs. Burton and Balmain also claim as reasonable and as having contributed to the recovery of their patient.

The real difficulty in these streptococcal fevers is to decide whether recovery has been *post* or *propter* the serum therapy. The most anxious cases may recover without serum therapy or many weeks after ineffectual serum therapy and in spite of serious complications such as Drs. Burton and Balmain describe. It is highly probable that the use of other types of sera was a factor in the recovery of their patient, but there is nothing conclusively in support of this in their clinical report as presented. One of our most striking recoveries followed treatment with combined polyvalent serum and scarlatinal antitoxin, but I should hesitate to claim that the recovery was directly due to it or that it could not have occurred without it.

I am in entire agreement with their plea for early blood-culture and for a fuller trial of treatment with various types of concentrated serum, but if we are really to advance our knowledge of serum therapy in acute bacterial diseases such as septicæmia and lobar pneumonia, the most careful study of the natural history and course and of the variable mortality of these diseases, and the most critical analysis of case-reports are necessary. Better standards for distinguishing between *post* and *propter* effects must also be evolved. I am, Sir, yours faithfully,

J. A. RYLE.

Wimpole-street, W., July 11th, 1931.

MORTALITY AFTER PROSTATE OPERATIONS.

To the Editor of THE LANCET.

SIR,—Dr. Minnitt comments on the rise of the blood-urea figure following ether anæsthesia, and apparently concludes that it is an important factor in the mortality after prostatectomy, and that for this operation spinal anæsthesia should be substituted. He quotes an operative mortality of 50 per cent., which is greatly in excess of that obtained from any other source.

In his Lettsomian lectures, Sir John Thomson-Walker gave statistics from 11 general hospitals, in which the total mortality in 3451 cases was 19·5 per cent. The mortality at St. Peter's Hospital from 1901 to the end of 1929 was 9·9 per cent. in 2691 cases. For 1930 it was 7 per cent. It is only natural to suppose that a considerable number of these patients were operated on under inhalation anæsthesia (this is certainly true for the cases in St. Peter's Hospital), and I feel that ether cannot be blamed entirely for the mortality Dr. Minnitt encountered.

I have operated on almost 900 cases of enlarged prostate; about a third of them were given spinal, and the remainder inhalation anæsthesia. There was practically no difference in the mortality-rate of the two series, it fact it was a little higher when I used spinal anæsthesia. Before the war I employed this method in about 90 per cent. of my cases, but I gradually gave it up, and for the last eight years I have only used it occasionally. Spinal anæsthesia is ideal from the surgeon's point of view. It gives complete relaxation, and makes the operation easier than any other form of anæsthetic, but it has certain disadvantages for the patient. The most important of these is the fall of blood pressure. The average fall is about 30 mm. of mercury. With the addition of ephedrine the fall was about 15 mm., while when ether or gas-and-oxygen was used the blood pressure at the end of the operation was approximately the same as that before induction. This fall in blood pressure seriously diminishes the urinary excretion during the first 24 hours after operation, and it increases the risk of reactionary hæmorrhage.

My impression is that the mortality after prostatectomy depends more on the pre- and post-operative treatment of the patient than on any other factor. Most of the deaths ascribed to "uræmia" or "renal failure" are really due to post-operative pyelonephritis, which may not give rise to symptoms. Post-mortem records show that the kidneys are infected in most cases of post-operative "uræmia."

I have looked up the records of the last 150 cases I operated on in private. There were 5 deaths, 3·3 per cent. All these patients had inhalation anæsthesia. In 15 of them the operation took place in the country, the after-treatment being left to the local doctor; the remaining 135 were operated on in London, and remained under my care during their convalescence. There were two deaths among the country cases, 13·3 per cent., and three among those operated on in London—2·2 per cent. The operation was identical throughout, so the difference in the death-rate must be put down to the post-operative management. I am, Sir, yours faithfully;

Harley-street, W., July 11th, 1931. J. SWIFT JOLY.

CANE AND BEET SUGAR.

To the Editor of THE LANCET.

SIR,—In 1914 a small book was published on "Heart Disease and Cane Sugar," by the late Dr. A. Goulston, and there was some correspondence on the subject, mostly confirmatory of the author's conclusions, in the medical journals. Briefly, he stated, and supported his arguments by numerous cases, that he had found extra sugar alimentation to the amount of not less than 2 oz. and up to 6 oz. of *cane* sugar daily of very great value in the treatment of failing hearts. His first paper was published in 1911, and some of the cases he quotes are from other practitioners who, as a result of this paper, had tried the sugar treatment with excellent results. I myself tried it both in hospital and private practice, with considerable benefit to the patients, but the advent of the war, and the difficulty of obtaining sugar, made it impossible to carry it on, and later it had almost passed out of my mind.

The author insisted that the results were only to be obtained with *cane* sugar, not with beet, and gives two cases to support this point. To many, in those days, it seemed absurd that there should be any difference in the results given by two substances of identical chemical composition, but to-day our outlook is wider, and we are bound to admit that there may be bodies indefinable by chemical analysis, but of vital importance to the organism, in substances of identical composition but of different origin. The conditions under which cane and beet sugar, respectively, are produced—climate, soil, mean temperature, insolation, irradiation—differ enormously; it is reasonable to suppose that they may, therefore, have different physiological values. If they have, it is really of very great importance that we should know the facts.

As regards the heart, I venture to suggest that these could be determined by careful perfusion experiments.

At the present moment the English nation is engaged in the task of helping to destroy the colonial sugar industry by subsidising beet sugar in the interests of our own decaying agriculture. With the decline of Demarara and the West Indian plantations now rapidly progressing, it seems inevitable that the amount of beet sugar consumed here must increase. Doctors are not concerned with the question whether this demonstration of the difficulties of Imperial Preference is economically sound or unsound, but they should certainly know which of the two forms, in which one of our principal foods is taken by every man, woman, and child in these islands, has the better physiological value, if there be any difference between them. I submit that this might well be a subject of inquiry by the Food Investigation Board, the last number of whose Transactions rather suggests that in the future the coöperation of the biochemist (animal) and the biochemist (vegetable) in problems of this kind may produce valuable results.

I am, Sir, yours faithfully,

Wimbledon, July 6th, 1931. E. HOBHOUSE.

ACUTE RHEUMATISM FOLLOWING TONSILLITIS.

To the Editor of THE LANCET.

SIR,—The valuable paper by Dr. Sheldon and the interesting correspondence following it prompts me to draw attention to statements which occur in a paper which appeared in the *Medical Press and Circular* (1930, cxxx., 7), which I think bear on the subject in a way that may be useful to the discussion. In that paper I pointed out that all cases of throat inflammation are accompanied by some disorder of the heart, and further on stated: "In connection with an epidemic of the 'common cold' one knows that the throat inflammation has a tendency to clear up altogether, and no doubt the heart disturbance also disappears, but we all know that in some cases the throat condition may become subacute or chronic, and we ought also to know to what extent there is some residual disturbance of the heart. This linking up of throat and heart disturbances as part of one systematic serous disturbance is important for the point of view of ætiology, because it helps us realise that in both cases the exudative processes are upset."

Personally, I believe that acute rheumatism is due to a protozoon, of which the Aschoff body is the encysted form, and in the "acid children" who are predisposed to this disease the throat inflammation gives rise to a blood pressure conducive to the active generation of the protozoon. In all acute cases of acute rheumatism it will be found that the basic blood pressure is raised considerably before an attack, and with the return of temperature to normal the basic blood pressure becomes normal.

I am, Sir, yours faithfully,

Swansea, July 14th, 1931. G. ARBOUR STEPHENS.

MILLER GENERAL HOSPITAL.—According to the report for 1930 there has been a great improvement in the financial position as compared with 1920, when there was "a very real fear that part of the hospital would have to be closed." The building debt of £17,850 is being reduced by the interest from the gift of £20,000 from an anonymous donor to the King's Fund for the reduction of capital charges on voluntary hospitals in the boroughs of Deptford, Greenwich, Lewisham, and Woolwich. Last year there were 2140 new in-patients, a slight fall, explained by a small rise in the average number of days' stay (to 23·44 from 22·93), and to the children's ward having had to be closed twice owing to outbreaks of scarlet fever. The average weekly cost was £3 6*s.* 11*d.* At 30,123 the new out-patients showed a reduction of 1000, which was the more welcome owing to the inadequacy of this department. The old Congregational church which was converted into a temporary out-patient department ten years ago is showing signs of serious structural defects. A new building has therefore become an acute need. A coal-cellar is being used to provide additional accommodation for the X ray department.

BEIT MEMORIAL FELLOWSHIPS.

ANNUAL REPORT.

At a meeting of the Beit Memorial Fellowship, held on July 14th, the annual report for 1930 of the hon. secretary, Prof. T. R. Elliot, F.R.S., was adopted. The death, on Dec. 8th, 1930, of the founder of the Trust, was a great loss, for besides endowing the Trust with £210,000 in memory of his brother, Mr. Alfred Beit, Sir Otto Beit had devoted close thought to the advancement of the aims of the Foundation, and had shown the keenest pleasure in marking the successes in the advance of medicine by research which had been achieved by the most distinguished of the Beit Fellows.

On the expiration of his appointment as director of the Lister Institute, Sir Charles Martin, F R.S., had resigned from the Advisory Board of the Foundation after 21 years of loyal service. His resignation was deeply regretted, more especially since out of the 137 Fellows who had been elected since 1909 no fewer than 31 were assigned to work at the Lister Institute under his general direction, the Institute providing all laboratory facilities.

Sir James Kingston Fowler had resigned from the routine duties of honorary secretary, but the Foundation would retain his services as senior trustee; Sir James Kingston Fowler had been associated with the Foundation even before its inception, since he had taken part in the original discussions with regard to the contemplated benefaction and he had fostered each year's work with unremitting care.

The new appointments recorded were as follows:—Trustees: Sir John Rose Bradford, F.R.S., and Sir Alfred Beit. Advisory Board: Prof. J. C. G. Ledingham, F.R.S., and Dr. P. P. Laidlaw, F.R.S.

The number of Fellows at present working on the Foundation, excluding those reported for election now, is 23. The list of places recognised for research has long been widening, and each year more and more Fellows are being permitted, for special purposes, to work for a year abroad. The Fellows elected choose their own problems for research. The report calls attention to the fluctuations in the subjects proposed year by year, and to the rapidity with which the tide of research "swings first into one bay and then to another, in the pressure to find through allied sciences the means towards fresh advances in medicine. Bacteriology, for example, has so altered its landward approaches that among the present Fellows and the 39 candidates at this July election only a very few are content to attack the problems of microbic disease by the older charted ways. More of the voyagers now are exploring the coasts of biochemistry, and through fundamental studies, by precise test-tube experiments on the metabolic activities of bacteria, or on the modes of ferment action, are seeking to understand their behaviour in the human body. Indeed, for these and like aims, there are of the present Fellows seven now clustered in the biochemical laboratories of Cambridge University."

ELECTION TO FELLOWSHIPS.

The following new Fellows were elected:—

Senior Fellowships (value £700 per annum).

F. R. Winton, M.A., M.D. Camb. To continue his work in the Pharmacological Laboratory of University College, London, on the tonus of plain muscle, on the blood pressure in the glomerulus of the kidney, and on the effect of drugs on kidney secretion.

Fourth Year Fellowships (value £500 per annum).

B. H. C. Matthews, M.A. Camb. To continue his work in the Physiological Laboratory, University of Cambridge, on the analysis of sensory nerve impulses by electrical records obtained with the delicate oscillograph which he has invented.

Junior Fellowships (value £400 per annum).

Benjamin Stanley Platt, M.B., M.Sc., Ph.D. Leeds. Re-elected to the Junior Fellowship which he had resigned in 1926 in order to obtain medical qualification and so fit himself more fully for medical research. He will work at the School of Medicine, Leeds, on problems of the alimentary canal.

William Albert Hugh Rushton, Ph.D. Camb. Proposed research: On the chronaxie of nerve and muscle. Place of research: Physiological Laboratory, Cambridge.

Leonard Hubert Stickland, B.A. Camb., 1928. Proposed research: An investigation of the metabolism of the anaerobic bacteria associated with gas gangrene. Place of research: Sir William Dunn Institute of Biochemistry, Cambridge.

Muriel Elaine Robinson, Nat. Sci. Tripos, First Class in Parts I. and II. (Physiology), 1922. Proposed research: To continue investigations on hæmoglobin; and on the preparation of proteins in a pure state. Place of research: Sir William Dunn Institute of Biochemistry, Cambridge.

Frank Burnet Byrom, M.D. Lond., 1920; M.R.C.P., 1926. Proposed research: A study of factors influencing the total water exchange of the human body in health and in disease (in continuation of work begun at Chicago as Rockefeller Fellow). Place of research: The London Hospital.

Janet Maria Vaughan, D.M. (Oxf.), 1930. Proposed research: An investigation of the relationship of disordered hæmotopœisis to those bone changes that are found in human disease or which can be experimentally produced in animals. Place of research: Institute of Pathology, London Hospital.

Dr. C. H. Lambie, who held a Fellowship from 1923 to 1926, has been appointed to a new whole-time Chair of Medicine at the University of Sydney, New South Wales. Dr. D. Keilin, F.R.S., has been chosen for the Directorship of the Institute for Parasitology at Cambridge, to which he was first appointed to work as Junior Beit Fellow in 1920, and where he remained for a total period of seven years' research as Junior and Senior Fellow.

All correspondence of Fellows and candidates should be addressed to the Honorary Secretary, Beit Memorial Fellowships, University College Hospital Medical School, University-street, London, W.C.1.

Sheffield Royal Infirmary.—The governors are seriously considering the difficult pecuniary position of this hospital. Last year there was an adverse balance of £11,000, and during the first half of the present year the hospital is worse off than in 1930 by £3250. Should the situation not improve it may be necessary to close 80 beds, but an increase in the rate of contributions under the penny-in-the-pound scheme is under consideration on the ground that it is offering greater benefits than it can afford.

Valencia Island Hospital.—The tiny hospital on Valencia Island, county Kerry, is one of the few Irish hospitals in a position to extend in recent years without the aid of the hospital sweepstakes. The island is a meteorological station, and a station of the Western Union Telegraph Co. The hospital's patients include fishermen and farmers along part of the mainland coast, as well as those living on the island itself, and also the crews of trawlers and cable boats. Hitherto stretcher operation cases have been obliged to cross the ferry in an open boat to the mainland and to undertake a further journey of 40 miles to Tralee Hospital. There are days in winter when the ferry crossing cannot be made at all. The hospital contains eight beds in all; the largest wards for men and women holds three beds each, and there are sleeping quarters and a sitting-room for a resident matron. An operating theatre and an acetylene plant have now been added, and the hospital is about to be reopened. It is hoped that in the near future it will be possible to add a fever ward and a maternity ward—the latter, for very poor patients, is sorely needed. There is, however, a maternity and child welfare centre which is attended regularly by Dr. Elsie Murphy, the medical officer of health, and a nurse.

THE NATIONAL COLLECTION OF TYPE CULTURES.

EVEN the most superficial examination of the third edition[1] of the catalogue of the National Collection of Type Cultures, which has just been published, must impress the reader with the very considerable progress that has been made since the last edition[2] appeared in 1925. This collection, maintained by the Medical Research Council at the Lister Institute of Preventive Medicine, now comprises over 3000 different strains of micro-organisms of importance in human and veterinary pathology, plant pathology, agricultural and soil bacteriology, fermentation industries and also types useful for teaching purposes. The demand for cultures both at home and abroad has steadily increased, so that now considerably over 5000 cultures are distributed in each year to all parts of the Empire and beyond.

MICRO-ORGANISMS PATHOGENIC TO MAN.

A host of new types have been added to the collection in recent years. Among those of special concern in human pathology may be mentioned the extensive list of salmonella species, culturally similar but serologically distinct, that have been the subject of recent research by Bruce White, Schütze, Scott and others in this country. There has been acquired recently a valuable collection of pathogenic fungi belonging to the genera achorion, trichophyton, microsporon, actinomyces, madurella, sabouraudites, bodinea and others, including many types from the Sabouraud collection and also the isolations of Drs. Hare and Tate made during their researches on the fungi causing ringworm in children attending London County Council schools. Special mention may be made of *Actinomyces somaliensis* and *Madurella mycetomi,* which are associated respectively with white- or yellow-grained and black-grained "Madura Foot Disease" in the Egyptian Sudan (actinomycosis and maduromycosis of Chalmers and Archibald), the organism of "mossy foot" disease of the Amazon region (*Phialophora verrucosa*), the fungus of San Joaquin Valley Disease or coccidioidal granuloma (*Coccidioides immitis*), which has recently become a question of some concern to public health authorities in the New World, and *Scediosporium apiospermum,* the causal organism of a mycetoma in tropical South America and Southern Europe. Among the fungi may also be noticed *Penicillium notatum* Westling, a producer of "penicillin" and first used by Fleming in the elaboration of selective media for the isolation of Pfeiffer's influenza bacillus. A very fine selection of anaerobic bacteria, including the A and B types of *B. botulinus,* were presented to the collection by Prof. Ivan Hall in 1929. This also includes the interesting species *B. sordellii,* Hall and Scott, first isolated by Dr. Sordelli of Buenos Aires from lesions of malignant œdema combining the pathogenic properties of *B. novyi* (*B. œdematiens*) with some of the morphological and cultural characters of *B. sporogenes.*

The name "*B. indicus-ruber*" carries us at once back to the early days of bacteriology, and the catalogue reminds us that this strain, sent through the kindness of Dr. Robert Breed of the New York State Agricultural Experiment Station, was isolated from the alimentary canal of an ape in India by Robert Koch in 1884 during his researches into the ætiology of Asiatic cholera. But this is not by any means the *doyen,* so to speak, of the collection, for further on we find descendants of Duclaux's original isolations of "*Tyrothrix*" species from cantal cheese made in 1878, which were presented a few years ago by Dr. L. Rosenthal of the Pasteur Institute. Of interest also are the original isolations of *B. proteus* X 2 and X 19 made by Weil and Felix during their researches into the ætiology of typhus fever. Among the list of staphylococci one notices the Bundaberg strain of *Staphylococcus pyogenes,* isolated in connexion with the fatalities, still fresh in the memory, following the injection of toxin-antitoxin among children at Bundaberg, Queensland, and described in the report of the Royal Commission of Enquiry. Here also are Burnett's strains of the same organism, some of which are dependent on CO_2 for the production of toxin, while others produce toxin in its absence. Streptococci from scarlet fever are well represented, and include the original Dick strains (*Streptococcus scarlatinæ* I. and II.) used for the preparation of filtrates for use in the Dick intracutaneous test. Under streptococci may also be found specimens of the aerobic strains recently isolated from cases of puerperal sepsis, Birkhaug's non-methæmoglobi forming streptococci, and Small's strains of *Streptococ cardio-arthritidis* isolated from cases of rheuma fever. Under the genus neisseria (which also inclu the gonococcus and meningococcus) are listed strains of *Neisseria flavescens,* a new meningococcus-like organi isolated last year by Miss Sarah E. Branham of the U.S. Public Health Service from cases of epide meningitis. These organisms differ from the mening coccus in pigment production, lack of fermenta action and in antigenic relationship.

MICRO-ORGANISMS PATHOGENIC TO ANIMALS.

In the domain of veterinary science very extens additions have been made to the collection. T strains of *Actinobacillus lignieresi,* one of Engl and one of Swedish origin, are listed. These org isms were isolated from lesions of cattle su from actinobacillosis, a disease in many respec resembling actinomycosis caused by the true "ra fungus." One observes also *B. monocytogenes,* the causal agent of a peculiar disease of rodents associated with an absolute and relative increase of the mono nuclear leucocytes in the blood, isolated during a laboratory epizoötic at Cambridge in 1926 and described by Murray, Webb, and Swann. It is curious to note that a similar organism had been isolated the previous year from a South African gerbille, found dead and examined at the South African Institute of Medical Research by Major Harvey Pirie. Under the name *Bacillus welchii* are included two interesting sub-species. One of them, the bacillus of lamb dysentery isolated by Mr. T. Dalling, was presented by the Wellcome Physiological Research Laboratories; the other, isolated from lesions of sheep suffering from "struck" or "gangrene" was isolated by Mr. A. D. McEwen of the S.E. Agricultural College, Wye. One may regard these organisms as possibly separate and distinct species, but at any rate they are serologically distinct from *B. welchii* and from each other. Through the kindness of Lieut.-Col. Hamerton and Dr. Lovell, an interesting series of typical strains of "Morgan's No. 1 Bacillus" (*B. morgagnii*) has been made available. The organisms were isolated from cases of dysenteric colitis among animals at the Zoo, and came from such diverse sources as orang-outang, squirrel, and Abyssinian monkey, green-billed toucan, false moccasin, large-scaled mabma, and pine snake. *B. pseudotuberculosis-rodentium* is well represented, the collection containing a complete selection of Schütze's serological groups and types of these organisms. It is worthy of remark that this organism is non-motile when grown at 37° C. but is actively motile when grown at room temperature, the explanation being that the flagellated "H" form of the organism does not develop at the higher temperature, the non-flagellated "O" form only being present. A serological grouping is also presented by the genus pasteurella, which is here arranged according to the classification of Cornelius. Both with *B. pseudotuberculosis-rodentium* and with the pasteurella group there is no significant correlation between the species of the infected host and the serological type of the organism encountered.

MICRO-ORGANISMS AFFECTING PLANTS.

Of less interest, perhaps, to medical men and veterinarians are the sections devoted to phytopathology and fermentology, but to many others these pages will appear the most attractive. This side of the collection is becoming of increasing importance, for a continuous attempt is being made to satisfy the requirements of mycologists and technical bacteriologists in this country and to make them independent of other sources of supply. Many hundreds of new fungi affecting plants, many of high economic importance, have been added to the collection during the past few years, and a glance at the descriptive list forming Part II. at the end of the catalogue will assure the reader of the importance attached to this aspect of the collection. Here are listed parasitic forms attacking fruit crops, cereals and vegetables, tropical produce and timber, including not only representatives of the higher fungi but also many species of phytopathogenic bacteria. The latter are often closely related, both morphologically and serologically, to various common saphrophytic forms—e.g., *B. fluorescens-liquefaciens* and *non-liquefaciens*—from which they probably derived. In most cases, however, a specific pathogenicity for their host plants is not to question.

BACTERIA OF GENERAL INTEREST.

Among organisms of general bacteriological interest may be mentioned the very complete collection of aerobic spore-bearing organisms (to which many systematists consider the generic name "bacillus" should be strictly confined) presented by Dr. W. W. Ford of Johns Hopkins University, whose researches, and those of his co-workers, have done so much to clarify the taxonomic position of this difficult group. Also worthy of mention are Gray and Thornton's collection of soil organisms concerned in the decomposition of certain aromatic compounds (phenol, meta-cresol, and naphthalene), which are used as soil sterilising agents. Pure cultures of these bacteria use these compounds as sole sources of energy in mineral salt media containing inorganic nitrogen. Many interesting types derived from bacterial disease of insects, both harmful and beneficial, are conserved. Typical of the former may be instanced the *Coccobacillus acridiorum* of d'Hérelle, associated with locust disease, and of the latter, *B. paratyphosus-alvei*, the cause of "paratyphoid" of the honey-bee.

PROTOZOA.

Among the protozoa are several species of leishmania, isolated recently in the Near East—*L. agamæ*, isolated from heart blood of grey lizard (*Agama stellio*), Lower Galilee; *L. ceramodactylæ*, isolated in Bagdad from gecko (*Ceramodactylus doriæ*); and *L. tarentolæ*, isolated in Tunis from a similar host. These interesting types were deposited in the collection by Dr. S. Adler of the Hebrew University, Jerusalem. Worthy of remark also are the herpetomonas species, isolated by Noguchi and Tilden from hemipterous insects, and the latex of the milk weed on which they feed, which were used in serological investigations of leishmania and allied species of protozoa.

NOMENCLATURE.

Mention should also be made of the appendix to the preface which contains the resolution of the International Society for Microbiology with regard to the composition and scope of the newly formed Nomenclature Committee of this Society, together with the complementary resolution of the Plenary Congress of the Fifth International Botanical Congress. It is hoped that under the guidance of an authoritative international committee, created in such favourable circumstances, substantial progress and agreement may soon be reached on many difficult questions of bacterial taxonomy and classification.

MEDICAL NEWS

University of Oxford.

The Theodore Williams scholarship in anatomy for 1931 has been awarded to J. W. A. Turner, of New College. The Master and Fellows of University College have awarded the Radcliffe scholarship in pharmacology to D. F. G. Moir, of Magdalen College.

University of London

At recent examinations the following candidates were successful:—

D.P.H.

Part I.—Katherine Barnett, H. L. W. Beach, T. C. Lonie, G. R. Marcano, S. M. Rafi, A. M. Samarasinghe, C. R. Selous Jones, S. P. Srivastava, and Sarah M. F. Walmsley.

Royal College of Surgeons of England.

A quarterly meeting of the Council was held on July 9th. Lord Moynihan was re-elected president, and Mr. R. P. Rowlands and Mr. W. Sampson Handley were elected vice-presidents. Sir Arthur Keith was reappointed conservator of the museum for a further period of five years. Mr. R. H. Burne (physiological curator), Mr. C. F. Beadles (pathological curator), Sir Frank Colyer (honorary curator of the odontological collection), and Mr. C. J. S. Thompson (honorary curator of the histological collection) were re-elected. The Hallett prize for anatomy and physiology was awarded to Mr. S. G. Clayton, of King's College. The second Macloghlin scholarship for medical students was awarded to Mr. R. Y. Stevenson, of Herbert Strutt School, Belper. Mr. E. G. Muir, F.R.C.S., of Middlesex Hospital, was reappointed Bernhard Baron scholar, and the College research scholarship was granted to Mr. L. F. O'Shaughnessy, F.R.C.S. The Fellowship was conferred on Mr. A. A. Davis (Manchester), and Mr. A. L. Light (Leeds and Middlesex). Membership of the College was conferred on Harbans Singh (Punjab and St. Bartholomew's).

Licences in Dental Surgery were conferred on the following:—

Benjamin Bane, N. F. Bunn, John Bunyan, E. L. Clark, Brian Connelly, L. H. G. Cummings, J. C. Dominick, G. T. C. F. du Plessis, T. A. A. Eaves, M. W. Ellwood, C. L. Endicott, R. L. Etheridge, D. W. Goodman, W. G. C. Hackman, L. P. Harte, W. U. Harwood, R. N. Hines, K. A. Johnson, S. J. G. Knott, G. S. Loader, W. P. McEldowney, Alan Mortimer, Leslie Mortimer, W. L. Mountain, R. H. G. Neave, P. E. Probert, M. A. Rahim, J. L. Roberts, H. S. R. Sarson, J. A. Sidebottom, W. M. Sinclair, J. W. Small, Mervyn Snipper, J. H. Stevens, P. J. Stoy, J. V. C. Sutton, Marius Taralrud, R. W. Tuck, D. J. Wandless, and W. J. Wheatley.

Diplomas in Public Health, Psychological Medicine, and Laryngology and Otology were granted jointly with the Royal College of Physicians.

The following professors, lecturers, and demonstrators were elected for the ensuing year:—

Hunterian Professors.—Sir Arthur Keith, six lectures on Recent Advances in Embryology applied to Surgical Problems; Mr. J. P. Hosford, one lecture on Some Factors in the Causation of Hydronephrosis; Mr. R. T. Payne, one lecture on Excretion Urography; Dr. A. Remington Hobbs, one lecture on the

Puerperal Uterus as a Surgical Problem; Dr. J. A. Ryle, one lecture on the Natural History of Duodenal Ulcer; Mr. H. A. Harris, two lectures on the Comparative Anatomical Aspect of Prenatal, Infantile, and Adult Disease in Man and Animals, with special reference to Bone Growth.

Arris and Gale Lecturers.—Prof. W. E. Le Gros Clark, two lectures on the Structure and Connexions of the Optic Thalamus; Mr. A. J. E. Cave, one lecture on the Morphological and Functional Anatomy of the Human Cervical Spine.

Erasmus Wilson Lecturers.—Mr. C. E. Shattock, Mr. C. P. G. Wakeley, Mr. R. Davies Colley, and Mr. E. D. Moir.

Arnott Demonstrator.—Sir Arthur Keith.

Thursday, Nov. 12th, was fixed as the date of the Buckston Browne annual dinner of Fellows and Members.

University of Sheffield.

At recent examinations the following candidates were successful:—

M.D.

E. S. Clayton and J. N. Gale.

FINAL EXAMINATION FOR M.B., CH.B.

* J. E. Edson, A. W. R. Eardley, T. A. Hunt, S. K. Pannikar, and D. R. Rigg.

* With Second-class Honours.

University of Aberdeen.

On July 7th the following degrees and diplomas were conferred:—

M.D.—*B. S. Cran, Peter Henderson, and W. J. Webster.

* Awarded Honours for Thesis.

M.B. and Ch.B.—† W. G. Davidson, † T. N. Morgan, Annie S. Bain, C. L. Barron, John Brennan, J. A. Cardno, Alexander Chalmers, J. W. M. Christie, W. A. Clarke, W. S. Davidson, E. H. W. Duncan, E. W. Duthie, F. M. Duthie, G. I. G. Findlay, W. M. Fotheringham, Winifred I. B. Gibb, William Harkins, D. A. Macdonald, H. E. T. McDonald, William Mackie, Elizabeth A. Marsden, Alexander Matheson, J. F. Mitchell, C. M. McQ. Murray, M. G. Murray, L. R. A. Ogg, A. A. Peat, C. D. Preston, Isobel S. W. Ramsay, W. S. Russell, P. C. B. Shirreffs, J. D. Trail, and James Webster.

† With Second-class Honours.

D.P.H.—R. G. Henderson, Roderick Mackay, William Stewart, and Robert Sutherland.

Queen's University of Belfast.

At a graduation ceremony on July 10th the honorary degree of Doctor of Science was conferred on Dame Louise McIlroy, professor of obstetrics and gynæcology in the University of London, and Mr. Joseph Barcroft, F.R.S., professor of physiology in the University of Cambridge. The following ordinary degrees and diplomas were conferred:—

M.D.—J. H. Biggart,* Jane L. McNeill,* A. J. P. Alexander,† Eric Blackstock, A. E. Campbell, Kirk Forsythe, and J. W. Kernohan.

* Gold medal. † Commendation.

M.B., B.Ch., B.A.O.—Second class honours: Lilian V. Reilly, F. J. Booth, J. B. McKinney, and G. A. W. Neill. Pass degree: F. W. Atkinson, Basil Blewitt, Douglas Boyd, E. C. J. Camps, E. M. Condy, D. H. Craig, J. A. Crockett, R. S. Cromie, W. B. Davis, Edward Davison, N. S. Dickson, Joseph Eidon, John Halliday, H. A. Hezlett, Robert Johnston, G. A. Kane, J. J. G. Kerr, J. R. McAdam, Rowan McCombe, Grace E. McConkey, R. M. McMinn, D. W. Macartney, J. A. Magee, H. L. Martin, J. T. Murphy, Howard Nelson, D. J. P. Parker, J. W. Patrick, T. E. Reade, A. G. Ross, R. O'N. Sloane, Raymond Smith, H. D. Sutherland, H. A. Taylor, Gerald Townsley, A. P. Trimble, and T. W. H. Weir.

D.P.H.—Samuel Anderson, J. L. Bradley, Kathleen M. Cathcart, J. A. Crawford, J. A. D. Deeny, P. H. Deeny, Campbell Gardner, Gertrude M. Glenn, T. S. S. Hall, F. F. Kane, J. M. McClenchan, W. C. MacFaul, J. A. MacHugh, B. L. MacQuillan, Grace K. Pollock, and George Smith.

B.D.S.—Lloyd Dornan.

L.D.S.—J. J. A. Bowe, R. G. Chambers, W. B. Forgrave, Sadie Gault, W. A. McClements, D. I. Malcolmson, J. W. Robinson, W. S. G. Rodgers, S. R. Sheane, R. S. L. Sloan, Agnes Smiley, and W. E. Smyth.

The Sinclair medal in surgery was awarded to W. S. Campbell, and the Symington medal in anatomy to W. M. Loughridge.

International Orthodontic Congress.

The second International Orthodontic Congress will be held at the Savoy Hotel, London, from July 20th to 24th, under the presidency of Dr. J. H. Badcock. On the first evening, after the presidential reception, Prof. Elliot Smith will give a popular lecture on Evolutionary Tendencies Affecting both the Teeth and the Jaws. On the following evening there will be a reception by the President and Council of the Royal College of Surgeons of England at the College. On Thursday, July 23rd, a banquet will be held at the Savoy Hotel.

Boston Surgical Society.

At a meeting of this society, on June 10th, the Bigelow medal for excellence in surgery was conferred on Mr. G. Grey Turner, professor of surgery in the University of Durham. In presenting the medal, Dr. F. B. Lund, the president, said that the previous recipients were Dr. W. J. Mayo (1921), Dr. W. W. Keen (1922), Dr. Rudolph Matas (1926), and Dr. Chevalier Jackson (1928). After the presentation Prof. Grey Turner delivered a lecture entitled Some Experiences in the Surgery of the Œsophagus.

University of Dublin.

At recent examinations in the School of Physic, Trinity College, the following candidates were successful:—

M.D.

T. C. Foster, Bernard Moshal, and Albert Sachs.

M.CH.

T. J. Millin and H. A. Brittain.

M.A.O.

W. S. Dickson.

FINAL EXAMINATION FOR M.B., B.CH., AND B.A.O. (PART II

Medicine.—*Brian O'Brien, G. A. Wray, T. M. R. Ahern, D. B. Bradshaw, H. V. Tighe, J. B. Fleming, H. F. G. Irwin, F. C. Jackson, M. G. Leane, I. G. M'Intyre, D. G. Kennedy, A. D. Barber, D. H. S. Boyd, W. A. Hill, T. J. O'Sullivan, J. C. M. Brambell, J. L. Martin, N. H. Leask, R. C. Sutton, H. S. Mason, E. F. Burton, and Joseph Elliman.

Surgery.—*Margaret D. Gregg, Elizabeth K. Roberts, Brian O'Brien, T. F. O'Donnell, Marjorie L. Campbell, T. M. R. Ahern, H. V. Tighe, Charles Ryan, J. C. M. Brambell, F. C. Jackson, Ruth R. Armstrong, A. A. Lisney, W. A. Hill, M. G. Leane, and N. H. Leask.

Midwifery.—A. A. Cunningham, J. A. Wallace, R. D. Scott, L. L. Nel, E. W. West, G. F. Harris, H. J. Garland, and Fran King.

* Passed on high marks.

D.P.H.

Part I.—Harry Nelson, G. C. Dockeray, L. L. Griffiths, W. Speedy, Nora A. Stack, R. St. J. Lyburn, Jane A. M. Na and C. P. Wallace.

Part II.—G. C. Dockeray, W. D. Speedy, Harry Nelson, a Nora A. Stack.

D.P.M.

Part II.—G. W. M. Scroope.

The Osler Club.

At a meeting of this Club, held in London on July 12th, t eighty-second anniversary of Osler's birthday, Dr. W. Stok the mayor of Oxford, delivered the fourth Oslerian Oratio entitled Osler and Tuberculosis. Dr. A. S. MacNa proposed, and Dr. A. P. Cawadias seconded, a vote thanks. An exhibition had been arranged of some of Osle writings on tuberculosis.

Medical Society of Individual Psychology.

The annual general meeting of this society, preceded a dinner, was held at the Florence Restaurant on July Dr. O. H. Woodcock, the out-going chairman, who presi said that the list of members had quadrupled during last nine months. Dr. W. Langdon-Brown was ele chairman for the ensuing session, with Dr. F. G. Crooksh as editor, and Dr. Hilda Weber assistant editor of the p cations. Dr. Redfern, Dr. Robb, and Dr. James were elected to the committee. Dr. T. E. Lawson (to w applications for membership and information should addressed at 11, Chandos-street, London, W. 1) re-elected hon. secretary and treasurer.

Royal Medico-Psychological Association.

The annual conference of this association was held l week in Dublin. The President, who was installed in of on the first day of the conference, was Mr. Richard Leeper, resident medical superintendent of St. Patric Hospital, Dublin. On July 7th Dr. Ariëns Kappers, Amsterdam, gave a lecture to the association on t Function of the Layers of the Cerebral Cortex. Seve other papers were read, among them being one by D Bethel Solomons on Insanity in Relation to the Parturie State; one by Dr. J. R. Lord on Somatic States in Ment Disorders; and one by Prof. W. Burridge (Lucknow) on t Mechanism of Personality. On July 8th the Governors St. Patrick's Hospital gave an afternoon reception to t members of the Association and a large number of oth guests. St. Patrick's Hospital is the oldest mental hospit in Ireland, and owes its foundation to Dean Swift, fro whom it is popularly known as Swift's Asylum. It st occupies the original building, though considerably moder ised. On the evening of the same day the Associatio held its annual dinner in the Hall of the Royal College Surgeons. On July 9th the members of the Associatio were entertained to lunch by Messrs. Arthur Guinnes Son & Co., and to dinner by the Strollers' Club. O the 10th the President of the Association and Mrs. Leep entertained a large company of friends at a garden part in the grounds of the Royal Zoological Society, and in th evening the Governor-General and Mrs. McNeill held reception at the Viceregal Lodge. On July 10th, after short business meeting, the members went for a moto tour through County Wicklow.

The King has given directions for the reappointment o Sir Hilarion Marcus Fernando, M.D. Lond., as a member o the Executive Council of the Island of Ceylon.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS.

BILLS ADVANCED.

In the House of Lords on Wednesday, July 8th, the Royal Assent was given by Commission to a number of Acts, including the Sentence of Death (Expectant Mothers) Act; the Mauritius Loan (Guarantee) Act; the Ministry of Health Provisional Orders Confirmation (Manchester and South Staffordshire Joint Small-pox Hospital District) Act; and the Ministry of Health Provisional Order Confirmation (Aylesbury Joint Hospital District) Act.

HOUSING IN RURAL AREAS.

On July 10th, in the House of Commons, Mr. **Arthur Greenwood** (Minister of Health) moved the second reading of the Housing (Rural Authorities) Bill. He said that the scheme of the Bill was one to help necessitous rural district authorities. Clause 1 provided that only those rural districts would be eligible for assistance who could show that their financial resources were insufficient to enable them to make adequate housing provision. There were ample powers under the Housing Acts to deal with the recalcitrant or apathetic local authority. They were dealing with a clearly defined problem, that of the housing of the agricultural worker, and the people similarly circumstanced. The scheme was limited to the agricultural part of the rural districts as defined in the Housing Act, 1924. The scheme was to be worked through a special committee to be appointed shortly with the approval of the Treasury and a separate committee to be appointed by the Department of Health for Scotland. The committee would consider applications by local authorities and determine the number and kind of house in respect of which this additional assistance might be given. It would lay down the date by which the houses were to be completed, fix the rent at which the houses were to be let, and also fix the amount of the special al grant in respect of the houses which had been approved. It was necessary to establish a test of poverty for the areas which were to be assisted. It would be a double test—first, that the product of a 1*d*. rate was less than 5*d*. per head for the population, and, secondly, that the general district rate was more than 10*s*. in the £. The scheme was an emergency one, and the applications had to be in before the end of November. The assistance given under the Bill would be in the form of contributions payable annually for 40 years like the ordinary housing grant, and the county council contributions of £1 per house, permitted under the Housing Act, 1930, would be payable in respect of houses occupied by the agricultural population.

Sir **Kingsley Wood** criticised the Bill, which he said was an uninspiring, doubtful, minor, rather pathetic but typical contribution of the Government to the needs of the countryside.

HOUSING INFORMATION IN M.O.H. REPORTS.

After further debate,

Lieut.-Colonel **Fremantle** said there was a real danger in the precedent which this Bill would set. For the first time, instead of having a housing subsidy fixed by Parliament they were going to have a variable extra subsidy to be applied for certain very limited areas, which certainly were not most in need of housing reform, however much they were in need of housing improvement. The Conservative Party yielded to no one in their desire to improve housing conditions, and they welcomed any help given to the rural parishes. But it had been pointed out that the expense of this scheme would probably work out at something like £1000 a cottage in the long run. This tremendous expense, in order to build a few cottages, was not justified at the present time, however much it might have been justified in 1919–20. It was a mistake to suppose that because a house had been condemned as unfit for habitation it would never be fit for habitation. Medical officers of health—and he had been one of them—had always condemned houses where they were deficient in vital necessities, such as water-supply, sanitary accommodation, &c., but there were many old cottages that could be put right and made fit for habitation. It was for that reason that the Housing (Rural Workers) Act was passed, which had been found very useful when properly used. Provision was already made, quite apart from this Bill, for bringing pressure to bear on local authorities who did not do their work in connexion with housing or anything else, by the beneficent and far-sighted measure passed in 1929, which provided the only practical way by which local authorities could be dragooned—namely, by the pressure of the purse. It was felt that one great thing required in regard to housing was publicity regarding what was good and publicity regarding defects. It often happened that these things were not known. But there was one method which was always available to the Ministry of Health and to the public, and that was to make use of the annual reports of the medical officers of health. The Ministry could call for a definite survey of a particular area regarding housing, leaving aside for the time being the normal report on public health. He meant a survey by the medical officers of health, both in the districts and the counties. Such publicity would go a long way towards showing to all concerned what were the actual facts and needs.

The Bill was read a second time without a division.

UNHEALTHY DWELLINGS.

In the House of Lords on July 13th the Bishop of **Southwark** drew attention to the large number of persons who, in London and elsewhere, are now living in unhealthy underground dwellings, and asked for information as to the number of houses which the local authorities proposed to build in the next five years. He also asked if His Majesty's Government would appoint, in the interests of efficiency and economy, a central housing council to encourage and supervise the building of houses for the working classes; and he moved for papers. He said that the medical officer of health for the London County Council stated that there were about 30,000 basement dwellings in London which were unfit for human habitation, but in which 100,000 people were still living. Sudden and violent falls of rain flooded these basements; apart from that, they were always damp and dreadfully overcrowded. In some of the rooms four or five persons lived and slept. The results to health were deplorable. He was told that children who lived in basements were unhealthier than slum children. They suffered particularly from pneumonia and rheumatism. It was said that continued progress was being made in the closing of basements, but he found that in 1929 only 174 had been closed. In fact his information was that the occupation of basements was extending. He knew that in South London there were more basements in use now than there had been eight or nine years ago; and he was informed that this was happening all over London. The local authorities had power to close basements as sleeping places if they were proved to be unhealthy. Their powers should be extended to closing living-rooms in basements if unhealthy, as it was impossible by inspection to decide which rooms were used for living and which for sleeping. It was true that large numbers of the occupiers of these unhealthy dwellings did not desire to remove. That was due to some extent to the protection they received under the Rent Restriction Acts. Even for basements the rents were raised at once for new tenants. But his experience was that the majority of occupiers were anxious to remove if they could obtain better habitations. He asked the Government to urge local authorities to regard unhealthy basements as the first thing to be dealt with in their housing policy; to introduce legislation to strengthen the existing law, if it required to be strengthened, and to make inquiries and publish the results on the health of people living in basements.

DIFFICULTIES.

Lord JESSEL said that the local authorities in London fully sympathised with the views expressed by the Bishop of Southwark, but they realised that the question was surrounded by many difficulties. There was difficulty, for example, in condemning certain dwellings because they were not technically insanitary according to the law; and there was also the difficulty already referred to—namely, the tenants did not always wish to remove.

Lord BUCKMASTER said that if there were difficulties the local authorities ought to clear them out of the way; the difficulties, though grave, were not insuperable. What was the use of building new houses if the slum-dwellers could not afford to pay the rents? The slum problem would have to be approached on a far wider and broader basis than had yet been attempted. In that matter he was prepared to go any length, because he found it difficult to live easily when he contemplated the horrible conditions in which people had to live around him. It was perfectly clear that until the unrestricted birthrate could be controlled this problem would never be solved.

Lord DICKINSON said that according to the information at his disposal things were getting worse instead of better in this connexion. While the population of the County of London was decreasing the number of persons in the occupation of underground dwellings was increasing. The great difficulty was to offer the provision of alternative accommodation. He suggested that a definite survey should be made of basement dwellings, to be followed by a definite programme of providing alternative accommodation.

AGREEMENT IN PRINCIPLE.

Lord SNELL (Under Secretary for India) said that the Government were in complete agreement with the main principle of the Bishop of Southwark's speech. This was a problem of great urgency. He was advised that the powers possessed by the local authorities were adequate for dealing with it. Under the Slum Clearance Act of last year any part of a house, above or below ground, which was let separately could be closed for habitation if proved to be unhealthy. The local authorities must not be diverted from their systematic attack on bad housing conditions generally to one aspect of it alone; there was no short and easy solution along those lines. The great difficulty was to rehouse the people in the slums, and the closing of a basement did not provide a new site. The Housing Act of 1930 was an earnest of the Government's intentions to deal drastically with the whole problem of the slums. The outlook for building was not unpromising. Five years' building programmes had already been submitted by 280 local authorities, covering five-eighths of the population of England and Wales, who proposed to build 340,000 houses. The Government would not neglect to keep local authorities alive to their responsibilities in the matter, though they were aware that local authorities generally were generously responding to their appeal to make use of the new slum clearance powers and resources provided by the Act of 1930. In the opinion of the Government, the setting up of a central housing council suggested by the Bishop of Southwark would be unwise. The Government were watching the situation, and they believed that they were reducing the problem of slum clearance to manageable proportions, though much remained to be done.

The Bishop of Southwark withdrew his motion for paper

HOUSE OF COMMONS.

THURSDAY, JULY 9TH.

Maternal Mortality.

Dr. PHILLIPS asked the Minister of Health how many local authorities had now replied to his circular on maternal mortality, issued in December, 1930; how many of these proposed to make improvements in their services; which local authorities proposed to make no improvements; which local authorities had not yet replied; and what were the latest figures of maternal mortality in areas which made no proposals for improved services or had sent no replies to the circular.—Mr. GREENWOOD replied: The following is the information asked for: 139 local authorities have now replied to this circular, and of these 102 propose to make improvements in their maternity services, while 13 state that the circular is still under consideration. I am sending a further communication to those authorities who have not yet replied to the circular. The following authorities do not propose at present to extend their maternity services: Berks, Flintshire, and West Suffolk county councils; Chepping Wycombe, Colchester, Cowbridge, Eastbourne, Hereford, Hove, Lytham St. Anne's, Newcastle-upon-Tyne, Reading, Sutton Coldfield, Thornaby-on-Tees, and Wallsend borough councils; Kensington and Westminster metropolitan borough councils; Aberdare, Barking Town, Barry, Northfleet, Stone, and Tettenhall urban district councils and Tonbridge rural district council. As regards the la part of the question, the only available figures as to mater mortality are published in the Registrar-General's Statistic Review which gives the figures for each county and county borough.

Poor-law Relief.

Sir KINGSLEY WOOD asked the Minister of Health the number of persons in receipt of poor-law relief in Engla and Wales.—Mr. GREENWOOD replied: The total of persons in receipt of poor relief in England and Wal (excluding rate-aided patients in mental hospitals, casua and persons in receipt of domicilary medical relief only) o Saturday, June 6th, 1931, was 992,450.

Vaccination.

Mr. WINTERTON asked the Minister of Health, in vi of the recent cases of deaths and of blindness follow vaccination, whether he would consider the appointm of a representative committee of inquiry to inquire into whole subject and to report to Parliament.—Mr. GREENWO replied: The subject dealt with in my hon. friend's ques was fully investigated by the Committee on Vaccinat whose reports were issued in 1928 and 1930, and I do see the necessity for any further inquiry at the present

Mr. FREEMAN: Is the right hon. gentleman ab announce any decisions on the statement which he ma a year ago as to the whole administration of the Vaccinati Acts?

Mr. GREENWOOD: No, I cannot.

Mr. WINTERTON asked the Minister of Health wheth in view of the admission that the deaths of the twin childr of Councillor A. A. Furness, of South Wigston, near Leicest were due to post-vaccinal encephalitis, he proposed to tak any steps to prevent the further use of Government lymp in this district.—Mr. GREENWOOD replied: The answer i in the negative. I am advised that there is no reason to associate the deaths of these children with the use of Government lymph.

Deaths in Convict Prisons.

Mr. FREEMAN asked the Home Secretary how many cases of natural death, suicide, and attempted suicide, respectively, had taken place in the convict prisons, local prisons, and Borstal institutions, respectively, during the 12 months ended May 31st, 1931, giving age, sex, cause, and date in each case.—Mr. CLYNES replied: Of natural deaths there were 8 in convict prisons, 22 in local prisons, and 1 in a Borstal institution. Of suicides there were none in convict prisons, 3 in local prisons, and 2 in Borstal institutions. In compiling any return of attempted suicides there is always a difficulty in determining whether certain cases are real attempts at self-destruction or are merely feigned attempts, undertaken for some other purpose; but so far as can be ascertained, the number of cases which can properly be classed as attempts to commit suicide were in convict prisons 1, in local prisons 20, and in Borstal institutions 1.

MONDAY, JULY 13TH.

Pensions Ministry and Medical Treatment.

Major EVANS asked the Minister of Pensions whether he would produce and issue for general information a comprehensive and scientific record of the experiences and achievements of the Ministry in medical and surgical pheres, including treatment of wounds, disorders of the ervous system, and other diseases.—Mr. F. O. ROBERTS plied: A review of the Ministry's experience in the andling of the principal war disabilities has been prepared the Ministry for inclusion in the forthcoming "Official edical History of the War," which I understand will be sued at a very early date. I may add that I am entirely sympathy with my hon. and gallant friend's suggestion, d have already under consideration what further steps, any, can usefully be taken in this direction.

Army Recruits and Physical Unfitness.

Mr. LOUIS SMITH asked the Secretary of State for War hat was the percentage of those offering themselves for listment in the Army who were rejected in respect of ysical unfitness in each of the past ten years; and the tal number rejected in each of such years.—Mr. T. SHAW plied: The information is as follows:—

ecruiting ear ending n or about) ept 30th.	Number of men served with notice papers.	Total number rejected.	Number rejected for physical or medical reasons.	Percentage of men served with notice papers who were rejected for physical or medical reasons.
1921	106,071	58,343	51,021	48·1
1922	106,954	64,661	59,736	55·9
1923	86,039	53,491	49,550	57·6
1924	84,506	52,886	49,215	58·3
1925	89,277	56,228	52,207	58·5
1926	83,092	52,627	48,800	58·8
1927	83,814	54,195	50,396	60·1
1928	82,938	51,509	47,552	57·3
1929	72,268	43,023	39,359	54·4
1930	66,717	39,022	35,425	53·1
	861,676	526,285	483,291	56·1

Pensions and Final Medical Awards.

r. MARCUS asked the Minister of Pensions if he was re of the hardship caused by the granting of final rds in cases of recurrent disability, such as neurasthenia, poisoning, malaria, and others; and if he was prepared grant further consideration to ex-Service men whose ability might recur at any time after their final award finished, with a view to awarding them either treatment full allowances over a certain period or a further award nsion, conditional on the duration of a man's illness was directly due to one of the recurrent disabilities ned.—Mr. F. O. ROBERTS replied: A final award , under the statutory regulations, made until the man's ndition is reasonably stable, each case being considered its merits and in the light of expert opinion as to the rticular ailment or disease. In any event the man has right of appeal for a year to an independent appeal ibunal. If a condition due to war service subsequently lls for treatment, it can be provided and allowances can so be paid where they are justified notwithstanding that a nal award may have been made. If, as a result of such eatment, a final award should be found to have been riously erroneous as an assessment for permanent purposes, further grant of pension can be made under special anction.

Vacancies

For further information refer to the advertisement columns.

Aberdeen Royal Infirmary.—Jun. Asst. Surgeon.
Accrington, Victoria Hospital.—H.S. £150.
All Saints' Hospital for Genito-Urinary Diseases, Finchley-road, N.W.—H.S. At rate of £150.
Altrincham General Hospital.—Sen. and Jun. H.S. At rate of £150 and £100 respectively.
Beckenham, Kent, Bethlem Hospital, Monks Orchard, Eden Park. Res. H.P. At rate of £150.
Bedford County Hospital.—Asst. H.S. At rate of £130.
Birmingham P.H. Dept., Tuberculosis Section.—Asst. M.O. £400.
Blackburn County Borough.—Asst. M.O.H. and Asst. School M.O. £500.
Bradford Children's Hospital.—H.P. £120.
Bradford Royal Infirmary.—Three H.S.'s. Each £150.
Brighton, Royal Sussex County Hospital.—Cas. H.S. £120.
Brighton, Sussex Maternity and Women's Hosp.—Res. H.S. £130.
Bury Infirmary, Lancs.—Third H.S. At rate of £150.
Calcutta, Presidency General Hospital.—Second Res. M.O. Rs. 1000 a month.
Cambridge, Addenbrooke's Hospital.—Res. Anæsthetist and Emergency O. At rate of £130.
Chester, East Lancashire Tuberculosis Colony, Barrowmore Hall, Great Barrow.—Asst. M.O. At rate of £275.
City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—H.P. At rate of £100.
Connaught Hosp., Walthamstow, E.—Res. H.P. At rate of £100.
Coventry, Coventry and Warwickshire Hospital.—Res. Cas. O. £125.
Dreadnought Hospital, Greenwich.—Physician, for Dept. of Physical Medicine. 50 guineas.
Dudley, Guest Hospital.—H.S. and Asst. H.S. £200 and £170, respectively. Also Hon. Orthopædic Surgeon
Dumfries, Crichton Royal Mental Hosp.—Asst. Physician. £350.
Durham County Hospital.—Two H.S.'s. Each £150.
Durham University College of Medicine.—Jun. Demonstrator in Physiology. £250–£300.
East London Hospital for Children, &c., Shadwell, E.—H.S. and Cas. O. £125.
Essex County Council.—First Asst. M.O. £750–£800.
Exeter, Royal Devon and Exeter Hospital.—H.P. and H.S. to Special Depts. Each at rate of £150.
Gravesend and North Kent Hospital.—Jun. H.S. £100–£150.
Great Yarmouth General Hospital.—H.S. £140.
Harrogate Infirmary.—Sen. and Jun. H.S.'s. At rate of £150 and £125 respectively. Also H.P. At rate of £150.
Hertford County Hospital.—H.P. At rate of £150.
Hove, Lady Chichester Hospital.—Jun. H.P. At rate of £50.
Huddersfield Royal Infirmary.—H.S. At rate of £150.
Hull Royal Infirmary.—3rd H.S. At rate of £150.
Inverness, Royal Northern Infirmary.—Two H.S.'s. Each at rate of £100.
Ipswich, East Suffolk and Ipswich Hospital.—Cas. O. £120.
Kent Education Committee.—Temporary School Medical Inspector. 12 guineas per week.
Kidderminster and District General Hospital.—H.S. £150.
King Edward Memorial Hospital, Ealing, W.—Sen. and Jun. Res. M.O.'s. £250 and £150 respectively.
Kingston-upon-Hull, City and County of.—Sen. Asst. M.O.H. for Maternity and Child Welfare Dept. £800.
Lancaster Royal Infirmary.—Jun. H.S. £130.
Leamington Spa, Warneford, General Hospital.—Hon. Surgeon for Diseases of Ear, Nose, and Throat.
Leeds Hospital for Women.—H.S. At rate of £100.
Leicester Royal Infirmary.—Sen. M.O. for Venereal Diseases Dept. £500.
Liverpool Eye and Ear Infirmary, Myrtle-street.—H.S. to Ophth. Dept. £120.
Macclesfield, Cheshire County Mental Hospital, Parkside.—Asst. M.O. £350.
Manchester, Ancoats Hospital.—Res. M.O. and H.P. At rate of £150 and £100 respectively.
Manchester, Manchester and Salford Hospital for Skin Diseases.—H.S. At rate of £100.
Manchester Victoria Memorial Jewish Hospital, Cheetham.—Jun. H.S. At rate of £125.
Margate Royal Sea Bathing Hospital for Surgical Tuberculosis.—H.S. At rate of £200.
Newcastle-upon-Tyne, Newcastle General Hospital.—Two H.P.'s and three H.S.'s. All at rate of £150.
Newcastle-upon-Tyne, Royal Victoria Infirmary.—Whole-time Jun. Surg. Reg. £150. Also Sen. Surg. Reg. £100.
Northwood, Mount Vernon Hospital.—H.S. At rate of £150.
Nottingham General Hospital.—Cas. O. At rate of £200.
Port Said, British Hospital.—Res. Asst. M.O. £375.
Portsmouth, St. Mary's Hospital, St. Mary's Institution, &c.—Second Asst. Res. M.O. £300.
Reading, Royal Berkshire Hospital.—Res. Anæsthetist. At rate of £150.
Rotherham Hospital.—Cas. H.S. £150. Also H.P. £180.
Royal College of Physicians, Pall Mall East, S.W.—Streatfeild Research Scholarships. £250.
Royal Northern Hospital, Holloway, N.—Asst. Pathologist. £500.
Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—Hon. Urological Surgeon.
St. John's Hospital, Lewisham, S.E.—H.S. and Cas. O. Each at rate of £100.
St. Leonards-on-Sea, Buchanan Hospital.—Jun. H.S. At rate of £125.
St. Thomas's Hospital Medical School, S.E.—Sen. Demonstrator in Anatomy. £500.
Salisbury General Infirmary.—H.P. £150.
Scunthorpe and District War Memorial Hospital.—Res. Surgeon. Also second H.S. £250 and £150 respectively.
Sheffield, Children's Hospital.—Whole-time Med. Registrar-Pathologist. £350. Also 3rd Res. M.O. At rate of £80.
Sheffield, Jessop Hospital for Women.—Asst. H.S. At rate of £100.
Sheffield Royal Hospital.—Cas. O. and Res. Anæsthetist. At rate of £150 and £80, respectively. Also Ophth. H.S. £120.
Sheffield Royal Infirmary.—H.S. and Second Asst. Cas. O. Also Ophth. H. S. Each at rate of £80.
Southampton, Free Eye Hospital.—H.S. £150.
Southport General Infirmary.—Jun. H.S. £150.
South Shields, Ingham Infirmary.—H.S. £150.
Stafford, County Bacteriological Laboratory.—Bacteriologist. 12 guineas per week.
Staffordshire, Longton Hospital.—H.S. £120.
Swansea General and Eye Hospital.—H.P. £150.
Swindon and North Wilts Victoria Hospital.—Res. M.O. At rate of £125.
Tynemouth.—Asst. M.O. for Poor Law Institution, Preston-road, North Shields. £300.
Walsall General Hospital.—H.P. At rate of £150.
Windsor, King Edward VII. Hospital.—Hon. Asst. P. to Out-patient Dept.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Teddington (Middlesex), and at Higham Ferrers (Northants).

Vacancies are announced for a Physician and a Surgeon as Medical Referees under the Workmen's Compensation Act, for Circuit 31, County Courts, Abercynon, &c.—Applications should reach the Private Secretary, Home Office, Whitehall, not later than August 5th.

NOTES, COMMENTS, AND ABSTRACTS

MENTAL INEFFICIENCY AND ADOLESCENT CRIME.*

BY W. NORWOOD EAST, M.D., M.R.C.P. LOND.,
ONE OF H.M. COMMISSIONERS OF PRISONS.

THE Mental Deficiency Act of 1927 has been in operation long enough to enable some of the diagnostic difficulties arising from the statutory definitions of mental defectiveness to be reviewed. A clear appreciation of those difficulties is of particular importance in criminal cases, and is essential for accurate testimony.

The distinction of idiocy and imbecility from insanity has been recognised by law and medicine for many years. The term "feeble-minded," however, denoting a less severe grade of mental deficiency than imbecility, was introduced into medical literature somewhat tardily. The word "feeble-mindedness" appears in the "Dictionary of Psychological Medicine," edited by Dr. D. Hack-Tuke, and published in 1892, and the reader is referred to dementia, idiocy, and imbecility for information. But there is no mention of feeble-mindedness in any of the descriptions of dementia, nor in the article by the late Dr. G. E. Shuttleworth on idiocy and imbecility; and we are left to conclude that the word "feeble-mindedness" connotes these conditions.

Dr. W. Ireland,[1] in 1900, wrote:—

> "Idiocy is mental deficiency or extreme stupidity, depending upon malnutrition or disease of the nervous centres, occurring either before birth or before the evolution of the mental faculties in childhood. The word 'imbecility' is generally used to denote a less decided degree of mental incapacity. The term 'feeble-mindedness' is now much used in the United States of America, both in legal and medical documents, to denote both idiots and imbeciles."

Still later, in 1906, Dr. Maudsley[2] wrote:—

> "Idiocy is a defect of mind which is either congenital, or due to causes operating during the first few years of life, before there has been a development of the mental faculties, and may exist in different degrees; the person afflicted with it may have the power of articulate speech and manifest a limited degree of intelligence, or he may be utterly destitute of any semblance of intelligence and of the power of speech, being little more than a mere vegetative organism. Imbecility is simply weakness of mind owing to defective development, and may be of every degree of deficiency, moral and intellectual; on the one hand, passing by imperceptible gradations into idiocy and, on the other hand, passing insensibly into ordinary intelligence."

Before this, however, high-grade cases were recognised as a distinct group by some of those who were concerned with their supervision. Amongst these were the medical officers of English prisons, who for many years drew attention in their official reports to a class of prisoner they described as weak-minded, and it is clear that they had in mind people who were neither idiots, imbeciles, nor insane. Again, in 1889 the Report of the Royal Commission on the Blind, Deaf, and Dumb recognised a class of feeble-minded children other than imbeciles, and made a recommendation that they should be separated from ordinary scholars in public elementary schools. And when a Departmental Committee on Defective and Epileptic Children was appointed in 1896, the terms of reference expressly differentiated feeble-minded and defective children from idiots and imbeciles; and the Committee reported that the feeble-minded children referred to in their inquiry were a distinct class from imbeciles, and differed both from ordinary children and from imbeciles.

By 1904 the term "feeble-minded" was in general use, and the class of case to which it referred was recognised to be less defective than idiots or imbeciles. A Royal Commission was appointed that year "to consider the existing methods of dealing with idiots and epileptics, and with imbecile, feeble-minded, or defective persons not certified under the Lunacy Laws," and the Royal Commissioners recommended the use of the words "mentally defective" "as a general term indicative of all classes of mental disorders, thus displacing the word 'lunacy' from that position." They defined "idiots" as persons so deeply defective in mind from birth or an early age that they are unable to guard themselves from common physical dangers, such as, in the case of young children, would prevent their parents from leaving them alone. "Imbeciles" were persons who are capable of guarding themselves against common physical dangers, but who are incapable of earning their own living by reason of mental defect existing from birth or an early age. "Feeble-minded persons" were persons who may be capable of earning a living under favourable circumstances but are incapable from mental defect existing fr birth or an early age (*a*) of competing on equal term with their normal fellows; or (*b*) of managing them-selves and their affairs with ordinary pruden "Moral imbeciles" were persons who from an ea age display some mental defect, coupled with str vicious or criminal propensities, on which punishm has little or no deterrent effect. These definitio were modified in the Mental Deficiency Act, 19 as follows:—

> "Idiots—that is to say, persons so deeply defective mind from birth or from an early age as to be unable guard themselves against common physical dangers.
>
> "Imbeciles—that is to say, persons in whose case th exists from birth or from an early age mental defectiven not amounting to idiocy, yet so pronounced that they incapable of managing themselves or their affairs; or, the case of children, of being taught to do so.
>
> "Feeble-minded persons—that is to say, persons in wh case there exists from birth or from an early age men defectiveness not amounting to imbecility, yet so pronou that they require care, supervision, and control for th own protection or for the protection of others, or, in the of children, that they by reason of such defectiveness a to be permanently incapable of receiving proper ben from the instruction in ordinary schools.
>
> "Moral imbeciles—that is to say, persons who from early age display some permanent mental defect coupl with strong vicious or criminal propensities in which punishment has had little or no deterrent effect."

New Definitions Under the Act of 1927.

Experience in the administration of the Mental Deficiency Act suggested the desirability of certain amendments, and when encephalitis lethargica spread throughout Europe in 1918, and was in many cases followed by the post-encephalitic syndrome public opinion became aroused by the inadequate provisions which were available for protecting these patients and the public from the consequences of the moral changes which were induced by the disease. The Mental Deficiency Act of 1927 followed. Defectives are defined in Section 1 of this Act thus:—

> "Idiots—that is to say, persons in whose case there exists mental defectiveness of such a degree that they are unable to guard themselves against common physical dangers.
>
> "Imbeciles—that is to say, persons in whose case there exists mental defectiveness which, though not amounting to idiocy, is yet so pronounced that they are incapable of managing themselves or their affairs or, in the case of children, of being taught to do so.
>
> "Feeble-minded persons—that is to say, persons in whose case there exists mental defectiveness which, though not amounting to imbecility, is yet so pronounced that they require care, supervision, and control for their own protection or for the protection of others, or, in the case of children, that they appear to be permanently incapable by reason of such defectiveness of receiving proper benefit from the instruction in ordinary schools.
>
> "Moral defectives—that is to say, persons in whose case there exists mental defectiveness coupled with strongly

---

* Read at a Conference of Prison Medical Officers at the Home Office, March 28th, 1931.

vicious or criminal propensities and who require care, supervision, and control for the protection of others."

The Act further declares that "for the purposes f this section, mental defectiveness means a condition f arrested or incomplete development of mind xisting before the age of 18 years, whether arising rom inherent causes or induced by disease or injury." hese familiar definitions are given at length to llustrate the change that has taken place during ecent years in the conception of mental deficiency. We now deal with cases under this heading whom . D. Turner[4] graphically asserts belong to the otch-potch of conditions known as mental deficiency. We are not concerned with mental deficiency in hildren, nor with idiots who never appear in a criminal ourt; and since the diagnosis of imbecility presents o practical difficulties, it is only necessary to direct ur attention to-day to feeble-minded persons and moral defectives. Before doing so certain alterations n the Act of 1927 require consideration.

Mental defectiveness as now defined seems to refer o other cases than such as were deemed to be mentally efective by the Royal Commissioners appointed in 904. Nevertheless the conduct of a patient may be garded by one medical man as evidence of feeble-indedness, and by another practitioner of equal thority as the result of a psychosis—e.g., the ost-encephalitic delinquent, whose conduct is constantly dealt with by certification under the Mental eficiency Act, although in many cases the indications mental abnormality are those of mental disease d not defect. Marshall has pointed out that the st-encephalitic, naughty, restless child who, like ter Pan, never grows up, is suffering from psycho-otor excitement similar to that which may occur the course of an attack of mania of the manic-pressive type.[5] Further, it may be argued that e biogenic psychoses of adolescence fall within the finition of mental defectiveness. However this ay be, the Amending Act removes certain barriers hich formerly separated mental deficiency and sanity, and demands a wider conception of the nditions for which certification is desirable. And hereas certain medical men appeared to view mental ficiency in the light of the Act of 1913 in terms of tive brain structure, this, although true for ry amentia, is probably not so applicable to econdary amentia, where the emphatic criterion of ental defectiveness, as defined in the Act of 1927, defective mental functioning expressed by abnormal onduct and social incapacity.

A second important change in the later Act is the rovision that the defectiveness may be brought bout by disease or injury arising before the subject is 18 years of age. And it has been observed many times that patients who become affected after this age may be ineligible for the benefits of institutional care in consequence. In other patients the date of onset of ambulatory disease may be undetermined, and the diagnosis of mental defectiveness is abrogated in consequence.

A third noteworthy alteration is the omission of the word "permanent" from the definition of moral defectives in the Act of 1927. The omission avoids the rejection of post-encephalitic cases, for, in the present state of medical knowledge, it is doubtful to what extent the moral defects attributable to this disease are permanent. But the amendment sometimes embarrasses the medical examiner, and deprives him of a useful aid to diagnosis.

In dealing with criminal cases the practitioner must always be prepared to support his opinion under cross-examination in a court of law. Facts observed by himself can be substantiated with assurance. But the arrested or incomplete development of mind which is so pronounced that the subject "requires care, supervision, and control for his own protection and that of others," may be determined only by the history. Generally speaking, the medical man has no first-hand knowledge of this, and it is essential to test it as far as possible; otherwise harmless incidents may assume undue importance, and fictitious exaggerations or intentional inaccuracies, if accepted without caution and criticism, may lead away from truth.

The mental defect of the feeble-minded may be mainly one of intelligence; that of the moral defective may be expressed by defects of character and temperament, and overlapping may occur in either direction. Further, the physical, physiological, and sociological features of each case must be considered as well as the innate dispositions and emotional qualities. Moreover, the greater the intelligence defect the less are defects of character and temperament required for the diagnosis of feeble-mindedness, and the moral defective may show little or no defect of intelligence. Further, as the mental defect of the feeble-minded is a general and not a special defect, so the mental defect of the moral defective is a general defect of character and temperament, of the instinctive tendencies and their emotional qualities, and not a defect in any special or limited direction. But defects of character and temperament, expressed by peculiarities of conduct, are common to mental defectiveness, and to certain normal and abnormal mental states with which they may be confused.

The Differentiation of Clinical Groups.

At the outset we require a working conception of the normal mental state. This may be regarded conveniently as the usual mental reaction-type of individuals belonging to the same class and race and of the same education; normal conduct may be regarded as a composite abstraction, the result of their average variations. If we wish to go further and distinguish between the abnormal and the pathological, we may find assistance from C. Spearman,[6] who points out that "for most practical purposes the crux does not lie in settling whether a person is pathological or not; but whether he is too much so to be tolerated." Accepting this, we are faced with the fact that the behaviour of criminals, as well as of persons who are mentally pathological, has been found intolerable by others; and Spearman refers to the views of those who consider that criminals should be looked on only as mentally ill and punishment be abolished. A reply to this from those who have spent their professional lives in prison work might appear biased, so I again turn to Prof. Spearman, who writes:—

> "One answer to such a claim would be to make a general comparison between the denizens of the jail and those of mental hospitals. For although no single formal definition may serve as a reason to distinguish them adequately, and although certain individual cases might equally well be assigned to either residence, yet on the whole the two classes stand out distinctly enough. If any man really could not tell which class he had got among, we might safely prophesy to which of them he was heading."

Clinical psychiatry assists us in the differential diagnosis between cases of high-grade mental defectiveness and the symptom-complex of any particular mental disorder. Psychology guides us in our pursuit of character formation, and helps us to appreciate the temperamental faults which suggest mental defectiveness. But the present fluid state of psychology, the various schools of psychological thought, and the disputes among eminent psychologists concerning basic principles, may leave the inquirer dissatisfied with any single line of approach. The hormic, hedonistic, behaviouristic or other school of psychology may provide the most acceptable solution to any particular problem of criminal conduct, and the investigator may prefer to retain his psychological freedom in eclecticism. But many students of character, following the teachings of W. McDougall, A. F. Shand, C. Burt, A. G. Tansley, and others, perceive the essential factors of human conduct to be the innate instinctive dispositions, and their accompanying emotional qualities.

In criminal conduct the acquisitive, aggressive, sex, social, and self-preservative instincts are most frequently at fault, and with the associated emotions act with various degrees of strength in different individuals, and in the same individual at different times. Two or more instincts may be simultaneously in action, opposing or reinforcing one another, and certain life-histories seem to indicate an entire lack of one or other instinct. It is a matter of common observation also that, when the unusual strength of some particular instinct tends towards anti-social conduct, the individual learns to restrain its activities in order that he may adjust his life successfully. Although certain psychologists seem to have no place for the will in their explanation of human conduct, many practical observers find it necessary to postulate an agency, in addition to reason, by which the instinctive tendencies and the emotions become inhibited, and character and conduct modified.

The failure of delinquent adolescents to exercise the self-control demanded by social convention may indicate the incomplete or arrested development of mind which we call mental defectiveness. But it may be due to malnutrition of character, or failure to grasp the value of inhibition and develop a process capable of growth. Observation under experienced supervision, discipline, and training is sometimes necessary to determine whether the fault is due to mental defectiveness or whether the essential ingredients of character can expand and the subject become socially acceptable. As the growth of intelligence is slow in certain individuals, so, too, is character development delayed in others. A common manifestation of this fact is mental instability, which may remain a handicap throughout life, although the subject may become stabilised with the passing of adolescence if growth is resumed on lines which are favourable to social adjustments.

Certain observers hold that mental instability results from defect of mental function, others from excess. Dr. A. F. Tredgold,[7] bearing in mind the instability which is common in the early stages of dementia paralytica and arterio-sclerotic dementia, and that the neurones in these conditions have been shown to be deteriorated, feels justified in considering constitutional mental instability as due to an inherent defect of the controlling functions. On the other hand, emotional instability is a prominent symptom of exophthalmic goitre, in which the general symptoms are attributed by many observers to excitation of the sympathetic, and no material changes are to be found in the cervical sympathetic, brain, or spinal cord.

It might be thought that the mental instability of adolescence would be amenable to organotherapy, in view of the important part played by the endocrine glands at this period of life, and the knowledge that a definite relation exists between their secretions and certain psychoses. The results of my own experience in treating selected cases of mental instability in juvenile delinquents on these lines have been discouraging. The complex reactions which cause the endocrine imbalance make the selection of a suitable therapeutic preparation experimental, even if the appropriate ingredients are capable of isolation in an active state and can be suitably combined. But the researches of biochemists lead one to hope that the treatment of certain cases of adolescent delinquency by glandular extracts may become established in the future.

The clinical manifestations of mental instability are excessive ideational, instinctive and emotional reactions, which, in severe cases, are so frequent and so little inhibited that social adaptation fails. If defects of intelligence are present also, the diagnosis of mental defectiveness is clear. If they are absent, the question arises whether the condition satisfies the rubric "mental defectiveness," whether the disproportionate reactions are due to an undeclared psychosis, or whether the symptoms indicate a transitory phase of adolescent growth.

The Constitutionally Inefficient.

If the controlling functions of the mind are known to have been impaired throughout the pre-adolescent period, and the environmental conditions have been entirely favourable, we can exclude with some degree of accuracy both pre-psychotic and transient adolescent instability, and have some reason to suppose that we are dealing with an inherent constitutional defect which may satisfy the statutory definition of mental defectiveness. But it seems proper to hesitate before a transitory delay in the development of character and control is stigmatised as mental defectiveness, unless enforced by the exigencies of any particular case. For all will agree that the Mental Deficiency Act of 1927 should implement the spirit of the Mental Treatment Act of 1930. Many cases of this nature can be determined only by the efflux of time, and the after-careers of some who improve temporarily show permanent defects when they are released from supervision. On the contrary, other cases who for years appear to be examples of permanent mental defectiveness recover later, and are then established as cases of delayed development.

The child of a bad-tempered woman was too nervous to read aloud at school, and when her teacher complained to her mother she was beaten, with the result that she became rebellious, wilful, and obstinate. She went into domestic service when 13 years of age, and stole a ring from her mistress; several thefts followed. She was eventually sent to an industrial school, and later to a reformatory. At this period she was reported to be a thief and a liar, and to exercise a bad influence on other girls. On her return home she worked for a time in a factory, but when 18 years of age was put on probation for sleeping out. She was sent to a home but ran away and returned to her parents but later took a young girl away with her to a distant city, where she was soon after arrested for being drunk and disorderly. She was then sent to a Borstal Institution where her conduct was so outrageous and her history so anti-social that she was considered to be mentally defective and was certified and sent to an institution for defectives. She became still more difficult, and was transferred to a mental hospital, whence she escaped twice. She was then sent to another mental hospital and escaped from there also, and did not come under supervision again until she committed another theft. Her records show that she was liable at this period to outbreaks of rage and violence for no apparent cause. She damaged the hospital property, assaulted the nurses, threatened the doctor, and attempted suicide. She was deceitful, and appeared to lack any [illegible] of right or wrong or of her social obligations, and [illegible] considered to be incapable of earning her own living. [illegible] soon after, during a period of detention in prison, [illegible] behaved well in spite of this.

Some time after her release, and when 25 years of age, she married a widower several years her senior. She was devoted to him and his child, and lived a happy, useful, and domesticated life for six years. Her husband was then taken to hospital for an operation, and she stole from a city store during this period of stress and when tempted by a former associate. She was sentenced to a short term of imprisonment, during which she conducted herself rationally, and was industrious, capable, alert, and intelligent. Her mental age was 13–14 years, her vocabulary 12,520 words. She was well informed on matters of ordinary interest and common knowledge, and discussed with me her past conduct with frankness and insight. She showed no evidence of emotional disturbance, and had a clear appreciation of her moral obligations. Her perception, judgment, and reasoning were good. I found no evidence of mental defectiveness or mental disease. She was, in fact, stabilised. The mental conflicts of childhood were apparently responsible for the anti-social conduct of subsequent years, but were now replaced by harmony and maturity and consequent social adjustment. Perhaps a different view might have been taken in the past if her medical examiners had been able to obtain her coöperation and appraise the emotional stresses which contributed to the anti-social conduct of her early life.

I say "contributed" advisedly. For, as Devine[8] points out, "the behaviour of an individual is determined by the prolongation into the present of his past experiences; by his inherited peculiarities; by his physiological state; by the rhythm of his vital processes and the various transformations of the reproductive functions; and by the manifold life situations with which he is confronted." The history and later examination of this woman indicated a variation from the normal, over and above her early temperamental faults. For she stole on the last occasion when temptation was not excessive and the environmental disharmony was insufficient ordinarily to cause delinquency. This difference is perhaps best described as a constitutional psychic inferiority, limiting the term to those who, through some defect in their mental make-up—usually of volition—are most aptly placed between the temperamental defectives and normal individuals.

Offenders of this clinical type belong to no special age-group and their offences are chiefly of a minor character. They are entirely different from the active, determined criminal whose forcefulness, initiative, and resource outrage society. Many habitual offenders fall into this group, although they may not be recognised during adolescence until efforts at rehabilitation by relations, friends, and after-care associations prove ineffectual. They usually adapt themselves successfully in a penal institution, and are often shrewd, able, and willing workers under supervision, and may intend to reform. But they follow the line of least resistance in the outer world and drift without anchorage. And although they may appreciate their social obligations and possess foresight and discrimination, they are incompetent to deal with situations which demand the suppression of temporary desires—not, seemingly, because the instincts and emotions act with overpowering force, but from passive inadequacy to negotiate life according to social conventions and the law's demands. The will is impotent. The striving for superiority Adler [9] asserts "is an intrinsic necessity of life itself. It lies at the root of all solutions of life's problems, and is manifested in the way in which we meet these problems." It however leaves them unconcerned.

These subjects belong to the subnormal group of inefficients, and the medical witness cannot testify under cross-examination that they are mentally defective. Their failure in life is apparently the result of a limited and not a generalised defect, and the observer cannot demonstrate evidence of mental defectiveness as a result of his own examination. Also, he must remember that "the diagnosis of mental deficiency may be established without a full history from the data observed by the medical examiner, but it can never be firmly sustained, however much it may be suspected, on the evidence of history alone." [10] Moreover, it would seem that the medical witness is unable to testify that the condition is essentially due to an arrest or incomplete development of mind, however strongly he believes it to be due to the failure of a particular mental function. And, still further, he cannot exclude from many cases the influence of a disadvantageous environment or unfavourable upbringing, although he may exclude effects arising from disease or injury before the age of 18.

(To be continued.)

A HOSPITAL FOR FUNCTIONAL NERVOUS DISORDER.

THE ancient foundation of St. Luke's Hospital now concentrates its activities mainly on the Woodside Nerve Hospital, which was opened in November last for the reception of cases of functional nervous disorder.[1] The Earl of Athlone, the new president, visited the Woodside Nerve Hospital on June 30th, and was received by the treasurer, Lord Blanesburgh, the committee of governors and such of the honorary consulting staff as were able to be present. Celebrations at the University of Leeds, however, prevented the presence of several of the latter, including Sir John Bland-Sutton, Sir Farquhar Buzzard, Sir John Rose Bradford, Lord Dawson, and Sir Humphry Rolleston.

The hospital stands in some 6¾ acres of ground, overlooking Highgate Woods, and has accommodation for 50 patients, 20 men and 30 women. Most of the rooms in the ward blocks are single bedrooms, and all of them face south, each one opening on to a broad verandah. There are also some private sitting rooms. The treatment block contains rooms for hydrotherapy, colon lavage, massage, light and electrical treatment. There are also in this block dental and X ray rooms, a photographic dark room, a dispensary, and large laboratories equipped for investigation and research. All the capital expenditure in building and equipping has been borne by the St. Luke's Hospital Foundation; but its resources are unequal to the heavy cost of maintaining the new hospital. This must therefore be borne to a great extent by the payment of patients according to their means. At the present time a minimum charge of 5½ guineas a week is made on each bed, two guineas extra being charged for a single room. At the same time every effort is made by means of rebates on these charges, allowed at the discretion of the Committee, to make the resources of the hospital available for those of limited means. The charges are inclusive of all necessary forms of treatment, the only extras charged being for personal laundry, special nurses, and such personal comforts as are not generally included in treatment.

During the six months that the Hospital has been open 65 patients have been admitted, and it is stated that the majority of those discharged have gone out recovered.

THE CORNER OF GOWER PLACE.

THE new building of Messrs. H. K. Lewis, at the corner of Gower-street and Gower-place, is now complete, and was shown to distinguished visitors at a reception held on July 9th. Sir Gregory Foster, formerly Provost of University College and Vice-Chancellor of the University of London, recalled his student days, when Lewis's consisted of a single house with a total frontage of 25 feet and one shop, about 15 feet by 16 feet, which used to be uncomfortably crowded with students at the beginning of every term. The architectural future of the corner of Gower-street and Gower-place, the site occupied by the new building, had always been an anxiety to the college authorities; now all anxiety had been set at rest by the way in which the rebuilding had been carried out. University College, he said, was fortunate in having at its doors an institution which provided real help in its educational work, and he congratulated "Lewis's" on the high traditions of sound service maintained by their firm.

Prof. H. R. Kenwood gave an address on Text-books and Education, and Mr. H. L. Jackson, the chairman of Messrs. H. K. Lewis, Ltd., commented on the functions of manufacturers and distributors of books. So long as they sought to make the pathway between the producers and the consumers of books as smooth and as easy and as inexpensive as possible they performed a useful service. A word of praise from Mr. Percy Flemming, F.R.C.S., for the facilities offered by Lewis's circulating library concluded the addresses, and the guests were given an opportunity to inspect the attractive new premises.

PITUITARY CYST.

IN the paper with this title, by Dr. Ranyard West, on p. 69 of our last issue, the first reference should read:—

THE POINTS OF CONTACT IN ELECTRIC SHOCK.

In a paper published in 1927,[1] R. W. I. Urquhart adduced evidence that when an electric current passed through the brain a block was produced in the respiratory centre; if the heart were not severely damaged, artificial respiration should save the patient by giving the respiratory centre time to recover. Survival has been recorded even after eight hours' artificial respiration.[2] In a later communication[3] Urquhart, with E. C. Noble, showed that a similar block might be produced in the lower part of the spinal cord of a decerebrate cat, and even in peripheral nerves, by an alternating current. Last year O. R. Langworthy and W. B. Kouwenhoven demonstrated[4] that severe electrical currents, when passed through the brain, might cause permanent injury to the cells of the respiratory centres. They now describe experiments[5] on the respiratory damage caused by currents which do not flow directly through the brain.

They used rats, in which the heart is especially resistant to damage by electricity. The results indicate that a current passing through the cervical part of the spinal cord, or through the chest, may cause a suspension of respiration through a temporary block in the vagus nerves; a current passing through the hinder part of the body is much less likely to produce this effect. The authors propose to undertake a histological examination of the central nervous system of all the rats in this series in order to see whether cell change has taken place where the current has not passed through the brain. Of course with the shocks used—1000 volts for two seconds—much damage may be caused by heat alone. The continuous current caused more severe burning, and seemed to cause more cell damage. When passed between the two forelegs both kinds of current killed all the rats and caused much burning and destruction; when the current was passed from a foreleg to a hind leg 41 per cent. survived the alternating current, but all needed artificial respiration; when from a foreleg to the tail only 67 per cent. needed artificial respiration with the alternating and 54 per cent. with the continuous current, and when between the two hind legs none of the rats shocked with alternating current stopped breathing, though 29 per cent. of those shocked with the continuous current required artificial respiration.

It must be remembered, as Langworthy and Kouwenhoven point out, that respiratory block is not the only cause of death—perhaps not even the chief cause—from electric shock in man. In many cases, particularly of shock from low voltages, the cause is believed to be ventricular fibrillation. They quote the experiments of D. R. Hooker,[6] who succeeded in arresting ventricular fibrillation with injections of potassium chloride solution.

TRELOAR CRIPPLES' HOSPITAL, ALTON.—The National Sunday League has presented to this hospital a ward in the new Connaught block in memory of the late Mr. Henry Mills. A ward has also been presented by the Chine Helpers of Southampton.

A NEW CLINIC FOR RHEUMATISM.—The London General Omnibus Company's Employees' Friendly Society has set up a clinic for the treatment of rheumatism, together with dental surgeries, at 61, South Side, Clapham Common, S.W. The house has been adopted and equipped at a cost of over £7000, and the clinic, which was opened by the Minister of Health on July 3rd, is being administered in close association with Manor House Hospital, Golders Green, under the direction of Sir Ambrose Woodall, the senior surgeon.

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, July 20th, to SATURDAY, July 25th.—MILLER GENERAL HOSPITAL, Greenwich-road, S.E. Intensive Course in general medicine and surgery. Two weeks, daily 10.30 A.M., to 5.30 P.M., demonstrations, lectures, operations. For either week.—Further particulars from the Fellowship of Medicine.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.

MONDAY, July 20th.—10 A.M., Gynæcological Ward Visit. Genito-Urinary Operations, Skin Department. 11 A.M., Surgical Ward Visit. 2 P.M., Surgical Ward Visit. Medical, Surgical, Eye, Gynæcological Out-patients.

TUESDAY.—9.30 A.M., Operations. 10 A.M., Medical Ward Visit, Dental Department. 11 A.M., Throat Operations. 11.30 A.M., Surgical Clinical Demonstrations. 2 P.M., Medical, Surgical, Throat, Out-patients, Operations, Medical Ward Visit.

WEDNESDAY.—10 A.M., Medical Ward Visit, Children's Medical Out-patients. 2 P.M., Medical, Surgical, and Eye Out-patients. Gynæcological Operations. 4.45 P.M., Venereal Diseases.

THURSDAY.—10 A.M., Neurological Department. 11.30 A.M., Treatment of Fractures. 2 P.M., Medical, Surgical and Eye Out-patients. Genito-Urinary Department Operations.

FRIDAY.—10 A.M., Medical Ward Visit, Skin and Dental Departments. 12 noon, Medical Lecture. 2 P.M., Medical, Surgical, and Throat Out-patients. Operations.

SATURDAY.—9 A.M., Throat Operations. 10 A.M., Medical Ward Visit, Surgical and Children's Medical Out-patients.

CHARING CROSS HOSPITAL MEDICAL SCHOOL POST-GRADUATE COURSE.

SUNDAY, July 19th.—10.45 A.M., Mr. H. E. Batten: Various Forms of Club Foot. 11.45 A.M., Mr. J. Brigh Bannister: Some Common Disorders of the Menopause.

ST. MARK'S HOSPITAL, City-road, E.C.

THURSDAY, July 23rd.—4.30 P.M., Mr. E. T. C. Milligan: The Injection Treatment of Piles.

UNIVERSITY OF BIRMINGHAM.

TUESDAY, July 21st.—3.30 P.M. (at the General Hospital) Dr. H. Featherstone: Basal Anæsthesia.

FRIDAY (at the Children's Hospital).—3.30 P.M., Dr. B Tate: Eczema in Infants and Children.

Appointments

BAIRD, D. I., M.B., Ch.B. Edin., D.P.H., has been appointed Asst. Medical Officer of Health, Blackburn.

BLISS, T. P., M.B., Ch.B. Edin., Certifying Surgeon under the Factory and Workshop Acts for Mauchline, Ayr.

LEARMONTH, A. G., M.B., Ch.B. Edin., Asst. Medical Officer, Stirling.

Births, Marriages, and Deaths

BIRTHS.

ATKIN.—On July 7th, the wife of Dr. C. S. Atkin, The Glen, Sheffield, of a daughter.

GIBBERD.—On July 7th, at Welbeck-street, W., the wife of G. F. Gibberd, M.S., F.R.C.S., of a son.

SMITH.—On July 6th, at Cullingworth, Broadstairs, the wife of R. Wylie Smith, M.B., B.Chir., of a daughter.

WORSELDINE.—On July 10th, at Stonefield, Blackheath, the wife of Stanley C. H. Worseldine, Captain I.M.S., of a son.

MARRIAGES.

FAULKNER—WARDE.—On July 9th, at Plymouth, Odin T. Faulkner, C.M.G., Director of Agriculture, Nigeria, to Mildred Warde, M.S., F.R.C.S.

WALKER—DIPLOCK.—On July 11th, at the Parish Church, Croydon, Geoffrey Secker Walker, M.A., M.B., B.Ch. Oxf., Reading-road, Farnborough, Hants, to Joan, only daughter of Mrs. Diplock, of Barclay-road, Croydon, and of the late Mr. Hubert Diplock.

DEATHS.

ANDERSON.—On July 2nd, at a Manchester nursing home, George Reinhardt Anderson, M.B.E., J.P., F.R.C.S., of 45, Westbourne-road, Birkdale, Southport, aged 67.

CROSS.—On July 12th, at Worcester House, Clifton, Bristol, Francis Richardson Cross, F.R.C.S., J.P., LL.D., following an attack of influenza, aged 83.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages and Deaths.

ADDRESSES AND ORIGINAL ARTICLES

PUBLIC HEALTH—TO-DAY AND TO-MORROW.*

By W. G. Willoughby, M.D. Lond., D.P.H. Camb.,

MEDICAL OFFICER OF HEALTH FOR EASTBOURNE; PRESIDENT OF THE BRITISH MEDICAL ASSOCIATION.

This is the first occasion on which a full-time medical officer of health has held the position of president of the British Medical Association, but preventive medicine has formed from time immemorial an important part of the work of every branch of the profession. The existence of the medical officer of health and of the public health service is due to a very great extent to the fact that at all times members of the profession have observed and recorded the direct and contributory causes of disease, and have studied how disease generally, and diseases in particular, can be prevented. The Ministry of Health and medical officers of health are systematically applying and extending the results of these observations and records.

As regards the past, I will only briefly remind you of such evidence of progress as the increase in the expectation of duration of life, the decrease in the general death-rate, and in the infant mortality-rate, the disappearance or lessened occurrence of some diseases, the mitigation of the severity of many others, the wholesale advance in the skill, technique, and safety of surgery, and the improved provision for the care and prevention of sickness. The most casual observation shows the great improvement that has occurred. In spite of abundant evidence of progress, however, it is not possible to be satisfied with the position of the general health to-day.

Public Health To-day.

The medical officer of health regularly receives from the registrar of births and deaths copies of all certificates of deaths, and also receives notifications of certain illnesses—so far a definite and generally accurate summary of those events in his district. He knows the extent to which ailments are affecting elementary and some other school-children, and persons who attend certain clinics. He also has less definite, but abundant, information as to other illnesses that are occurring in his district. It is his duty to act in connexion with this constantly recurring mass of information, and his consequent sense of responsibility has sometimes rendered the medical officer of health in his plans for improvement vulnerable in the eyes of general practitioners to the charge of removing his neighbour's landmark. Such concentrated and depressing information is not so constantly before those members of the profession who are dealing for the most part with individual patients.

The medical officer of health has also to study the mass of statistical information supplied to him weekly, quarterly, and annually by the Registrar-General, and this also makes a conscientious officer more restive. Without going into many figures from these and other statistics, there are some facts to which I wish to draw attention that indicate very clearly how much room there is for improvement in the public health.

The annual statistical summary of the Registrar-General for England and Wales demonstrates that there are far too many deaths at early ages. The *expectation of life*, according to the Registrar-General's last life-table, is still only 55 years for males and 59 years for females, and though the vitality of the nation has been steadily improving generally, the life-tables show almost no change at the ages of adolescence; from 30 years onwards there is but a slight increase in vitality, while at 50 the increase in expectation of life is only about two years. At advanced ages the progress is even less. In fact, the greatest part of the increase is due to the reduction of infantile mortality after the first week of life.

We are still on an average far short of the 70 years of the Psalmist. We are also faced with the position that his pessimistic description of the age-group 70 to 80 of his time applies far too truthfully to many of the years short of 70 in a great proportion of our population of the present day.

Illness and Physical Defect in Early Childhood.—An increase in the expectation of life is worse than useless unless the life so prolonged is healthy enough to be enjoyed; sickness makes it too often a doubtful blessing. The large amount of illness which must have occurred coincidently with 40,000 deaths in one year of young children who escaped the risks of infancy, while serious in itself, must also have been a leading cause of the indifferent health and permanent physical defects of so many of the survivors in their later years. Damage-rate is more important to the survivors than death-rate. Of elementary school-children an average of 8 to 10 per cent. are unfit to attend school owing to illness, and 1 in 5 of those attending has some physical defect. It is noteworthy that the children arriving at school at the age of five are already affected; the percentage of ailments is substantially diminished before they leave. Much of the neglect of defect at the pre-school age cannot be overcome, and will still have its injurious effect when the children become adults. A few years ago I made an investigation into the history of 504 mentally retarded children of this district who were not mentally deficient. The apparent causes were multiple in most instances, but early ill-health was the definite cause of the retardation in 47 per cent. of the cases, and a contributory cause in most of the others.

Health of Young Adult Population.—As examples of the unsatisfactory position to-day of the general health, early deaths and sickness in early life stand out prominently; other examples are the vast amount of sickness shown by national health insurance reports, and the wholesale rejection of young adults who have tried to enter the Navy, Army, and Air Force Services. During the war only 36 per cent. of would-be recruits between the ages of 18 and 42 qualified for active service. This unsatisfactory position still obtains. To a question in the House of Commons last year the Secretary of State for War replied that in 1929 5 per cent. were rejected for diseases of the middle ear, and over 4 per cent. for diseases of the heart. Defects of the lower extremities, dental defect, defects of vision, and insufficient weight caused rejections in each case of 2 to 3 per cent. The defects too frequently pointed to some illness or neglect in early childhood. The only marked improvements compared with the figures of 1910 were in dental condition and chest measurements.

As regards the sickness statistics connected with National Health Insurance, in any year an average of about half the insured population comes under treatment by insurance medical practitioners. The claims for sickness and disablement benefit have increased continuously, and have practically doubled in recent years.

---

* Abridged from the presidential address delivered before the British Medical Association at Eastbourne on July 21st.

These are only some few examples of the state of the public health. Other examples include the multiplicity of hospitals, and the enormous sale of patent medicines.

The Future.

In considering the outlook for the future the nature and constitution of the public whose health is to be improved is of primary importance. Owing to the reduction in the birth- and death-rates we now have to deal with an increasingly older population than in the past. This is due mainly to the decrease in the number of young people, for the life of the older generations is being prolonged but slightly. The average age in England and Wales at the 1921 census was 30·6 (males 29·9 and females 31·2). Ten years previously it was two years less, and in 1891 four years less. Corresponding figures for the 1931 census are not yet available in detail, but it is obvious that the change is now even more marked.

As the population becomes older the prospect of a further reduction in the death-rate becomes less and less.

REDUCTION OF THE BIRTH-RATE.

The constitution of the population is altering also through the nature of the reduction of the birth-rate. If careful, scientific, and eugenic birth control were possible, a healthier type might be evolved. What is actually occurring, however, is a greater proportionate reduction in the number of births among the better types of the race than among the less satisfactory. This results in a mental and physical disadvantage to the race as a whole.

Recent reports of the Board of Control show that the proportion of mental defectives in the population has increased approximately from 4 to 8 per 1000 in 25 years, and this fact is only partly explained by such reasons as better ascertainment and notification of the mental defective. Birth control is at its minimum among these people, and they seem especially fertile. Although it is sometimes asserted that heredity accounts directly for a relatively small proportion of mental defectives there is also indirect influence. In my own limited experience of such cases the parents are mentally defective in about 14 per cent., and on the borderline in another 16 per cent. or more. The descendants of these people, if the direct influence of heredity is escaped, are often permanently damaged mentally and physically by the consequent evil environment of their early life. Persons with a tendency to mental defect react very readily to environment, the mental defective being usually amoral rather than immoral.

If the present course of birth reduction continues, as it probably will do, we are nearing the time when the already diminishing natural increase of the population —that is, excess of births over deaths—will disappear entirely. The annual rate of increase by excess of births over deaths per 1000 living, which was over 14 50 years ago, and about 12 at the end of the last century, in 1928 was 5, and in 1929, 2·9. In the present difficult circumstances this may be satisfactory, but in venturing rightly or wrongly to interfere with the course of nature by birth control it is certainly essential to take care that in reducing the quantity of our available supply for the future of the race, we at all events endeavour to preserve the quality of the remainder.

FACTORS UNFAVOURABLE AND FAVOURABLE.

An alteration in the constitution of the population connected with the great decrease in infantile mortality has been caused by the survival of a large number of children who would otherwise have died. A selection depending on ignorance and neglect, however, is not a natural selection, but a very artificial one. Moreover, the enlightened preventive treatment which has resulted in so much saving of infant life has necessarily brought up the standard of life of infants generally.

Accidental deaths occurring in dangerous occupations, the migration of good types of individuals to other countries, unemployment, the development of unfavourable habits largely connected with diet, liquid and solid, are among the factors which affect the public health adversely. On the other hand, the good effects of education are to be seen in the improved condition of the elementary school-children, the increased importance attributed to physical training and open-air life, and the improvement of sanitation and housing conditions among the population as a whole. If the lay press, with its enormous circulation, would reproduce in popular form such definite facts as are to be found in the reports of the Ministry of Health and of the Medical Research Council, the progress would be more rapid. Sensational accounts of so-called cures for such diseases as cancer and tuberculosis do real harm. The hopelessly contradictory nature of advice so freely given as to eating and drinking prevents much notice being taken of it.

The Medical Profession and Public Health.

As regards the influence of our own profession on the future of the public health, we can be optimistic. Medical practitioners, in accordance with their traditions of progress, are taking an increasing interest and a greater part in preventive medicine than at any previous period. Thanks to the work of our Association, the spirit of friendly coöperation between the branches of the profession has steadily grown, and artificial barriers have been removed. In recent years there has existed a small committee of eminent and representative leaders of the profession to confer with the Ministry of Health on public health matters should occasion arise. General practitioners and medical officers of health coöperate in their work more and more as years go on. In this county borough, as in many others, there are quite a number of practitioners who, in addition to the preventive work carried on in the course of their own private practices, are giving valuable assistance in the public health service.

In its early days the public health service and the activities of the medical officer of health were almost entirely confined to the environmental circumstances of disease, a few infectious illnesses, and the application of discoveries that had been made in connexion with such essentials as pure air, pure water, and pure food. These duties of the medical officer of health are as important as they ever were, but new obligations have brought him into constant touch with members of the public as suffering individuals. This has arisen very largely from the number of persons, especially children, found to be suffering from defect, who for various reasons, especially want of means, received very little, if any, medical attention. It was found impossible to adhere to the principle that our duty should end when we had directed the sufferer or his guardians that the necessary medical services should be obtained, for though the advantages of the agency of the general practitioner for carrying out treatment were obvious, this was frequently not available.

The original allocation of large clinics in connexion with the public health service to men and women not long from their training schools was due to the obvious necessity for organisation and freedom from other calls on their time. These points could be secured with full-time clinic officers, but could not be obtained from those in practice. Though the preventive work of the general practitioner is by no means dependent on any work he may carry out in State clinics, modifications which enable him to take part in the treatment of patients in the State clinics are so clearly advantageous that there are signs of this coöperation being more developed in the future. On the one hand, the patients themselves are entitled to the benefit of his varied experience if this can be arranged, and on the other, the experience to be obtained from these clinics would be most valuable to him in his other work. The clinics, which have been an important factor in the improvement of the public health, would be even more useful if they could be coördinated with an increased general practitioner service in the homes of those not in a position to obtain that service at the present time. Early tendencies require skilled guidance, and environment requires skilled supervision; if these could be secured in the home, clinics for treatment would be less necessary.

It is essential that all ill-health should receive attention, and the B.M.A. scheme to extend facilities for treatment beyond the present insured persons is therefore of the utmost importance, and should receive careful consideration. The alternatives to a scheme on these general lines are either that nothing should be done for many sick people—and this is unthinkable—or that the arrangement of medical services should be made by laymen, and this would be most unsatisfactory for both the public and ourselves. It has been pointed out that if the best results are to be obtained it is important that in any form of clinic, contract, or insurance practice the relation between doctor and patient should remain as nearly as possible similar to that in ordinary practice.

While efficient diagnosis and treatment will always remain essential parts of preventive medicine, the improved arrangements now made for extending teaching in the subject of public health at the medical schools are extremely important. The General Medical Council has ordained that courses of instruction in forensic medicine, hygiene, and public health should be taken concurrently with the later stages of clinical instruction, and is still considering details. Public health has hitherto been a subject very detached from the other subjects of the curriculum. This arose from the also very detached nature of the original work of medical officers of health. As far as I am aware, the teaching of the subject of public health to students of medicine has reached its greatest elaboration in the McGill University. In the curriculum of this university the course of public health and preventive medicine has been divided so that in future a portion will be taken in each of the five years of the general course, and brought into close relation with the other work of the medical student in the corresponding year.

POST-GRADUATE STUDY.—AUXILIARY SERVICES.

In connexion with education, the facilities for post-graduate study are rapidly increasing. I would suggest that some simple extended opportunities could be made as a supplement to the present work and to the important scheme which is now in course of development. The work of the general practitioner is very largely concerned with minor ailments of children, maternity and child welfare, tuberculosis, and venereal diseases. There are clinics for these in abundance all over the country, and many more of them could be made available for instructive conference and consultation. The closer coördination of research work with clinical practice is essential.

The want of general application of existing knowledge is one of the many reasons for consideration of the scheme for extending the present limited opportunities of the medical practitioner to get into the homes for early advice and treatment. Since the study of physiology is an important part of the doctor's training, and needs special application to the individual from the time of birth, and before, I wonder if so much abandonment of so-called normal midwifery by the general practitioner is advisable. The only capable judge as to what is normal or abnormal in the working of the human mechanism must essentially have a good knowledge of physiology. The death returns show that the first week is the most dangerous period of human existence, and it must be beneficial to have the advantage of the doctor's knowledge from the earliest start of life.

An important indication of progress is the attention that is being given to bringing auxiliary medical services within the reach of an increasing number of the population. This is particularly the case with regard to consultant and specialist services. One of the latest of these is a scheme to make the valuable aid of pathological examinations available for those of moderate means. These developments are largely due to the activity of our Association, whose schemes also for the extension of medical services generally, and for improved midwifery services and hospital arrangements, require earnest consideration in connexion with the future of the public health.

It is necessary that members of the medical profession should take a leading part in the consideration of social conditions and ameliorative measures, for any matter that may affect the health must concern the profession. The presence of medical men and women in Parliament, on local government bodies, and in associations and societies that have any bearing on the subject of public health is therefore most advisable.

One of the methods, and not the least important one, of attaining the end we have in view—namely, the better health of the community—is by meetings such as the annual meeting of the British Medical Association, with its numerous scientific sections and social opportunities for interchange of knowledge and for debating the means of increasing and applying it.

LONDON HOSPITAL: ANNUAL REPORT.—Last year in-patients increased from 13,347 to 13,613, but the number of out-patients fell from 89,072 to 86,554. The fall is explained by the new arrangements made with the London County Council for the treatment of venereal diseases cases and to the greater use made at the instance of the house committee of the panel treatment of minor and trivial cases. The accounts show a deficit of £22,932, which would have been greater but for savings made by the general fall in the prices of provisions. Subscriptions and donations fell by £6525, but the Hospital Saving Association increased its contribution by nearly £2000. More than a quarter of the in-patients were members of the association, while nearly three-quarters of the total number of patients contributed, directly or indirectly, towards the cost of their treatment and maintenance. The amount so provided was £52,748, representing approximately 25·30 per cent. of the total income. The average cost per week and per inmate was £5 10*s*. 3*d*. and £14 0*s*. 5*d*.

GASTRO-PHOTOGRAPHY.

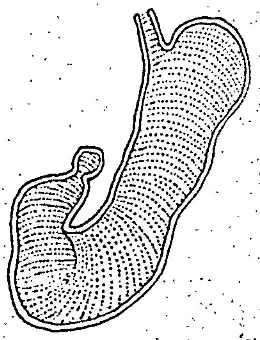
BY CHARLES A. PANNETT, M.D. LOND., F.R.C.S. ENG.,
SURGEON TO ST. MARY'S HOSPITAL; PROFESSOR OF SURGERY IN THE UNIVERSITY OF LONDON;

AND

DAVID LEVI, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO THE INFANTS HOSPITAL, VINCENT-SQUARE; DEMONSTRATOR OF ANATOMY, ST. MARY'S HOSPITAL MEDICAL SCHOOL.

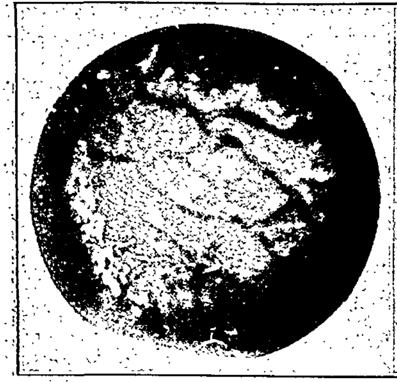
DIRECT inspection of the interior of the stomach by means of the gastroscope, as a generally applicable clinical method, would seem to be an unattainable ideal. With such instruments as we possess gastroscopy can never become a routine procedure. In many individuals it is associated with an unjustifiable risk. The difficulties to be overcome to make it safe are so apparently insuperable that it is no wonder that efforts have been diverted to the problem of obtaining a photographic image in substitute. Yet this itself has raised questions of extraordinary complexity, and only quite recently has a certain measure of success been achieved by the inventive genius of F. G. Back, an Austrian engineer, working in Prof. Wenckebach's clinic in Vienna, with Prof. Otto Porges and Dr. J. Heilpern. An instrument has been made which will, under conditions, give images of a large part of the stomach and the use of which is as free from danger as the passage of an ordinary stomach-tube. The gastro-photor, as the instrument is called, is a magnificent example of the application of the resources of science to a difficult and intricate problem. The object of this communication is to examine critically the possibilities of the device in clinical medicine,

FIG. 2.



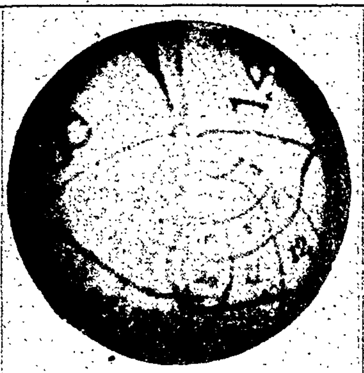
To show the shape of the air-distended stomach and how the antrum turns backwards at an angle to the general direction of the rest of the stomach.

FIGS. 1



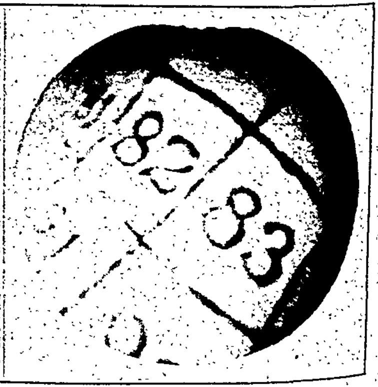
Photograph of the anterior wall of the stomach to show the definition which can be obtained with the gastric camera.

5



Lower antral picture of the cast.

6.



Lower ventral picture of the cast.

Some Fundamental Properties of the Apparatus.

To carry out any useful investigation with the gastrophotor it is essential to have an understanding of the essential principles of the apparatus and its physical possibilities. Its description has already appeared in several publications.[1] It suffices to say here that in its latest form it consists of two groups of four stereoscopic pinhole flashlight cameras, in each of which individual cameras face directions at right angles to each other, whilst being in the same horizontal plane. The two components of each stereoscopic camera are placed one vertically above the other. The angle of vision of each camera is so wide that it is possible to obtain images comprising the whole circumference of an enveloping container over a zone whose vertical width will depend upon the distance of its inner wall from the camera. The horizontal groups of cameras are placed with the nearest pinholes 30 mm. vertically apart, so that the two vertical zones also overlap unless the containing walls are very close to the pinholes. The images on the films are only 5 mm. in diameter, the enlarged prints from them have a diameter of 7·5 cm. But so brilliant is the flash and so sensitive the fine grained emulsion of the film, that it is possible to obtain prints of the definition shown in Fig. 1. However, the definition of the image depends to some extent upon the distance of the object from the pinhole. It falls off with increasing distance. The angle of the vision of the camera being so wide it naturally follows that the image of any particular object shrinks very quickly as it recedes from the pinhole, a fact necessary to keep prominently in mind in the interpretation photographs. The intensity of the flash has bee arranged to give a good exposure at the averag distance the stomach walls must be away from the pinholes to give pictures of a size which can be read and deciphered easily. It can be readily discerned how unfavourably the law of inverse squares acts in the case of the more distant areas of the stomach, which, unfortunately, often comprise just those areas the clinician would wish to inspect. Not only is definition poor and the image excessively small, but the illumination is nothing like the optimum to give the correct photographic exposure.

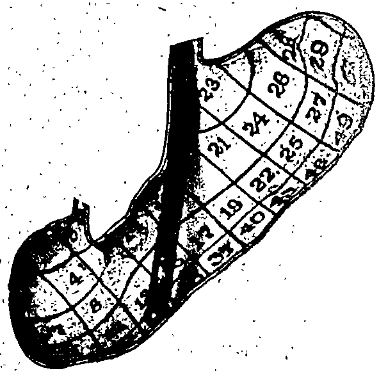
When the camera is placed properly in the stomach the pinholes of each group of cameras look forwards, backwards, to left and to right. The images obtained are described as upper or lower ventral, upper or lower dorsal, upper or lower fundal, and upper or lower antral.

FIG. 3.



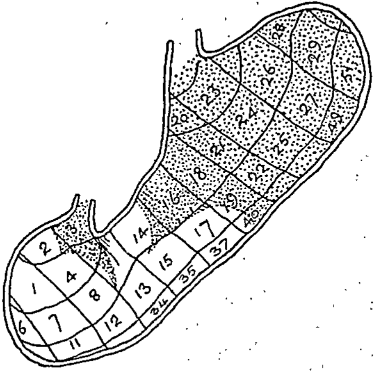
Photograph of the posterior half of the model of the stomach with the camera in position.

Suitability of the Camera for Photographing the Stomach.

The shape of the stomach differs very considerably in different people, as shown by X ray examination after the ingestion of an opaque meal. But the shapes thus revealed do not correspond with the air-inflated viscus which is photographed. The stomach, distended with air, approximates more to the shape of the organ described in the older anatomy books. In general it is to be considered as consisting of a large reservoir lying vertically or diagonally in the coronal plane of the body with a smaller antral portion which, as a rule, tends to turn backwards towards the spinal column (Fig. 2). The œsophagus passing into the stomach bears a little to the left, but a tube entering the cardiac aperture tends to be rather close to the lesser curvature. This can be seen very clearly in X ray photographs of the inflated stomach taken with the tube in position. In the diagrams (Figs. 7 and 8) it is seen that the camera cannot possibly give an image of that part of the lesser curvature, near the pylorus, and that in such a case the pylorus itself is not visible. This is one of the drawbacks of the apparatus; in but few cases can the pylorus and the whole of the lesser curvature be photographed.

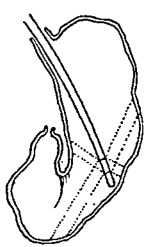
To get some idea of the general field of view covered a cast of an inflated stomach was taken. A mould prepared from this was split into anterior and posterior halves. The inner surface was then marked out into square inches, which were numbered. The camera was used to photograph the inside of the model. Fig. 3 is a photograph taken with the ordinary camera of the posterior half of the model with the telescopic camera in position. Fig. 4 is a drawing the shaded areas of which are those parts of the stomach of which images could not be obtained. More interesting than this, however, are the reproductions of the actual photographs, of which two are shown in Figs. 5 and 6. They are the lower ventral and the lower antral pictures. It is interesting to compare the sizes of the squares in the ventral photograph, where the camera was near the model wall, with some of the squares in the antral region. They are all of the same dimensions. The photographs also show what definition we may expect when contrasts are as great as black print upon a white ground. If we look at the lower antral photograph we see the brightly illuminated arch of the lesser curvature with the larger sized images contrasted with the more dimly lighted small imaged squares of the part of the antrum forming the greater curvature. The actual pylorus is invisible. It is unfortunate that we do not see any more of the lesser curvature, and that the definition of the pyloric region of the stomach fails from small size of the image and poor quality of the illumination. And although the whole area visualised is a large part of the stomach it is not all actually useful as far as practical medicine is concerned.

FIG. 4.



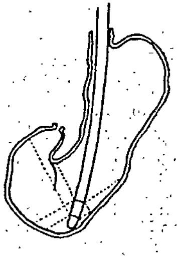
Depicts the area of the cast (dotted) which was not shown in the films when the camera was placed as in Fig. 3.

FIG. 7.



To show how the camera can be withdrawn from contact with the lesser curvature by bending the patient to the right.

FIG. 8.



To show how the camera may be made to advance along the greater curvature and thereby photograph more of pyloric region by bending the patient to the left.

Technique of Gastro-photography.

Though the apparatus has reached such perfection, we have found many pitfalls in the clinical application. Errors can creep in at every stage of the process, so that we cannot yet ensure at will a successful series of prints in every case. The preparation of the patient is important. His stomach must be empty for the examination. If any liquid should find its way into the camera the films will be spoilt. It suffices when the photograph is taken in the early morning to withhold food from the previous evening. In patients with much retention or with hypersecretion the stomach will have to be evacuated through a tube. Ryle's tube is not suitable for this purpose, owing to the small size of the holes, which are apt to be plugged by food remnants. To prevent liquid entering the apparatus during its passage through the œsophagus, a white paraffin wax is plastered into the crevices between the shutter and the camera itself. The introduction of the camera is made much simpler and easier for the patient if the pharynx and larynx be first sprayed with 5 per cent. novocain. This makes not the slightest difference, the prejudice against it being quite baseless. If novocain be used the whole procedure can be carried out with very little discomfort, whereas without it some individuals exhibit an impassable spasm at the entrance to the œsophagus, the attempt to overcome which will cause considerable pain. The camera will pass more easily if its rigid extremity be directed down the œsophagus with the finger. It may be lightly lubricated with the paraffin wax, referred to above, while the connecting rubber tube may be moistened with water. The instrument can usually be felt to pass through the cardiac opening, after which it is pushed on until it comes to rest, held up by the resistance offered by the greater curvature. Air is then blown into the stomach, the patient having been previously warned to signal when he feels distended, at which moment the photograph is taken and the apparatus withdrawn. A good result will not be obtained unless the inflation is sufficient.

X ray photographs of the camera in position show how it lies in the inflated stomach. It is very apt to lie close to the lesser curvature, so close, in fact, that it is not uncommon for no recognisable image to be obtained from the upper cameras facing antralwards. By bending the patient's shoulders to the right it is possible to increase the distance between the lesser curvature and the apparatus (Fig. 7), but this manœuvre will also carry it away from the most favourable position for seeing round the lesser curvature into the prepyloric region of the stomach, for which purpose it is better to have the patient's shoulders bent to the left (Fig. 8). All things considered, it seems more convenient to have the patient sitting up, but his back must not be allowed to sag. The lesser curvature may also be well seen in the left lateral position, with the pelvis and shoulders slightly raised. In the elongated variety of stomach a prolongation is screwed on to the extremity of the apparatus, otherwise, resting on the greater curvature, it would be too far below the lesser curve to get useful pictures.

Interpretation of Photographs.

The extreme variation in the size of images has already been referred to. It is one of the great difficulties of interpretation. It seems, however, that experience in reading photographs will tell here, and it is possible actually to measure the size of an image if a radiogram with the apparatus in position be made at the same time as the gastro-photograph. On the X ray film the image of the camera of known dimensions can be measured and calculations based upon the corrected distance of the object from the pinhole and the known distance of the film from the latter. This can only be an approximation, because the film distance varies somewhat, as the films themselves are not all accurately cut. Nevertheless, it is a useful approximation, and enables us to realise, as do Figs. 5 and 6, that a gastric ulcer, for instance, may have a very different aspect according as it is seen close to or from some distance.

We do not feel at this stage that we can be dogmatic about appearances seen through the eye of the camera. At first the photographs look like meaningless blotches. With increasing familiarity they undoubtedly take on significance. Sometimes, by a trick of vision, depressions have the appearance of projections and by not viewing the photograph as a whole from a sufficient distance we may perhaps fail to appreciate the forward bulging of the posterior wall of the stomach caused by the vertebral column or the bending round into obscurity of the lesser curvature. Much may be learned from the projection of shadows on the gastric mucosa, and the intensity of the illumination in the depths of hollows. The intense whiteness produced by light reflected from the surface of mucus is characteristic. It is helpful to make use of the knowledge of the appearances of the different parts of the stomach obtained by gastroscopy. It enables us to recognise the difference between the folds of the greater and lesser curvatures and other aspects of the mucous membrane. The deviations from this normal—for instance, the drawing together of these folds by cicatrisation round an ulcer—are the features by which abnormalities are recognised.

Conclusions.

It is difficult to assess this new method of gast[illegible] examination at present. It is certainly a great techn[illegible] achievement. It is also certainly sometimes capable of revealing abnormalities which remain concealed by any other method of investigation. Extended systematic study of gastric disorders is required. Light may be thereby thrown upon the different varieties of dyspepsia, the recognition of carcinoma may become possible in some instances at an early stage, before it is possible to discern its presence by other methods of examination. The drawbacks of the method are obvious. It is a highly complicated procedure requiring the utmost care at every step, and in the present stage of development cannot inevitably be made to produce results. It is a time-consuming examination. Only further study will show whether the gain is worth the immense trouble involved. As a means of research it is essential that it should be exploited. Doubtless its field of usefulness will be defined and experience will suggest alterations and simplification of technique. Such a safe method of gaining further knowledge of gastric pathology seems to offer distinct possibilities in the gastric investigation of digestive ailments.

We wish to thank Dr. H. C. Gage for his coöperation in the X ray work and Mr. W. J. Newly, who has been responsible for most of the photographic technical work, and to whose enthusiasm the success is in great measure due. Baron André de Veitschberger has throughout given us his guidance and the fruits of his experience; to him we wish to accord our grateful thanks.

THE DONORS OF FALMOUTH HOSPITAL.—The freedom of the borough of Falmouth has been bestowed upon Mr. William Mountstephen and Mr. Alfred Charles Collins, who between them bore the entire cost of the new hospital at Falmouth.

SOME RESULTS OBTAINED WITH THE GASTRO-PHOTOR.

By STANLEY WYARD, M.D., M.R.C.P. LOND.,
PHYSICIAN TO THE CANCER AND PRINCESS BEATRICE (FORMERLY KENSINGTON, FULHAM AND CHELSEA) HOSPITALS.

THE gastro-photor is an instrument whereby the interior of the human stomach can be photographed. By radiography after an opaque meal it has long been possible to reveal the size and shape of the stomach and any abnormality or irregularity in its outline; with the gastro-photor a permanent and visible record is obtained of the condition of the interior of the organ, though not of its size and shape. It is thus evident that radiography and intragastric photography supplement each other, and the new method may prove of great value in affording definite information in certain cases where radiography fails. The gastro-photor has been available in this country for so short a period that experience in its use is still very limited. The full extent of its powers has yet to be determined, but it is hoped that by its means it may be possible to reveal inflammatory changes in the mucosa, small non-penetrating ulcers, and ulcers about a gastro-enterostomy stoma when present. The reaction of an ulcer to treatment may also be followed and recorded.

Perhaps it may fulfil an even more important rôle. Precancerous changes are well recognised in certain situations; do they appear in the stomach? The relationship between simple ulcer and cancer is still in dispute, but it seems certain that cancer may arise quite independently of an ulcer. Will it be possible to demonstrate the earliest stage of such a growth and thus give the surgeon the best possible chance of eradicating the disease? It is clearly impossible to answer any of these questions at the moment, and the object of the present communication is merely to give some idea of the pictures which are obtained.

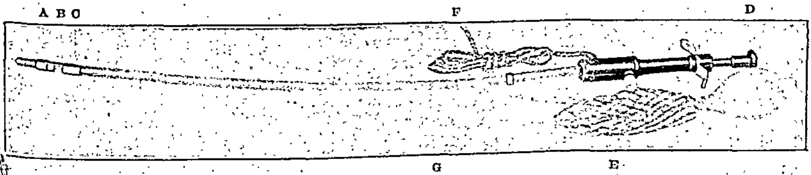
Use of the Apparatus.

The gastro-photor consists of two tubular metal cameras set at the end of an œsophageal tube. Each camera is divided into four compartments, and each compartment carries a photographic film. No lens is employed, but the image is focused on to the film by a pin-hole, which gives a more perfect definition than any lens. Each camera has eight pin-holes, so that each film receives two separate images, and 16 photographs are obtained by one exposure. Between the cameras an electric lamp is inserted and connected, through the œsophageal tube, with a transformer actuated from any electric lighting circuit having a voltage from 50 to 250, whether the current be alternating or direct. The pin-holes are covered by a sleeve moved by a Bowden wire passing up the tube to a handle at the upper end. When the cameras are in the stomach the handle is pushed down, causing the sleeve to uncover the pin-holes; a button on the transformer is immediately pressed, passing a current into the lamp so that the interior of the stomach is illuminated; finally the handle is released, allowing the sleeve again to cover the pin-holes, and the cameras are withdrawn. The whole operation only occupies two or three minutes.

FIG. 1 shows the instrument. A is the lower camera, carrying films 12×8 mm. C is the upper, with films 10×8 mm, so that the films can afterwards be readily distinguished. Between A and C is the lamp B. At the other end is the handle D, pressure on which exposes the films. By means of the bulb E the stomach is inflated immediately before the photograph is taken. The plug F connects the lamp with the transformer. G is a metal ring which slides along the tube to any desired position. The distance between B and G can be measured and then, if the ring be level with the patient's teeth, the situation of the cameras is accurately known.

The actual taking of a photograph is a perfectly simple operation; as with all these methods of examination, *it is the interpretation of* what one sees that presents a difficulty. Even in the most favourable circumstances this must be great until wide experience makes the observer familiar with the appearance of the gastric mucosa, but in the case of the gastro-photor two other factors add to it. In the first place, the negative obtained is only 3–4 mm. in diameter, and has to be enlarged 100 times, entailing more or less unavoidable loss of definition. In the second place a curved surface, the interior surface of the stomach, is focused on to another curved surface, the film in the camera, so that some degree of distortion of the image is inevitable. The two surfaces are curved in opposite directions, concavity towards concavity, which reduces, but does not eliminate, distortion. In spite of everything, however, many of the pictures show much detail, and the more pictures one examines the more detail one discovers in them.

FIG. 1.

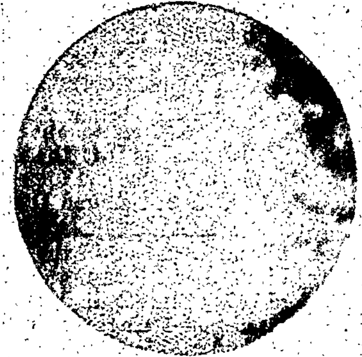


The Photographs.

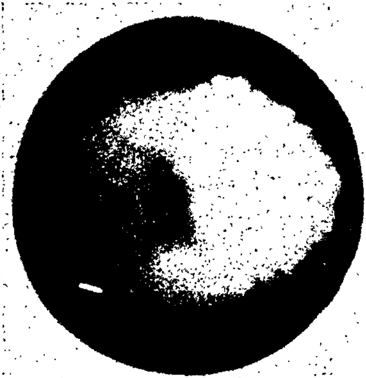
The illustrations are from photographs obtained from patients at the Cancer Hospital during the past two months. When the work was commenced much valuable advice and assistance was given me by Baron de Veitschberger, one of the co-inventors of the apparatus, who has had much experience with it in America. In examining a picture it will be found that a far better appreciation of its features will be *obtained* if it be held at some distance, 18 to 24 inches, than at closer range.

FIG. 2.—The normal rugæ of the gastric mucosa over the anterior surface of the stomach. Towards the upper part of the picture they are irregular and capped with a small amount of mucus; to the right and downwards they radiate outwards and

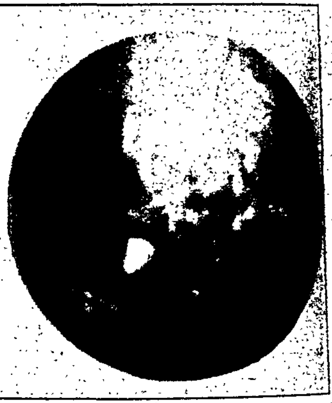
FIGS. 2



3



4.



have a matt appearance, owing to the absence of mucus (× 1½).

FIG. 3.—The pylorus, closed. The rounded margins and linear lumen suggest that the sphincter is contracted. There is much mucus on one side. No lesion was discovered in the stomach clinically, radiographically, or photographically (× ⅓).

FIG. 4.—Pylorus seen as it turns backwards beside the spine. One margin appears as a well-defined edge, suggesting that the sphincter is relaxed. At the upper limit of the orifice is a drop of mucus. Above the orifice the normal rugæ present a reticular arrangement. (× 1.)

FIG. 5.—A mass of mucus, containing large bubbles of gas, lying on the posterior surface of the stomach. Compare with Fig. 6. The reflection of light from the surface is much harder; little or none is absorbed. The aspect nearer to the observer is not illuminated, and the large bubble nearest but one to the left casts a definite shadow. The mucus is situated on a surface which, to the left, is curving away backwards. The patient was suffering from gastritis associated with a deeply penetrating ulcer (shown photographically in Fig. 10, and radiographically) on the lesser curvature. (× ⅓.)

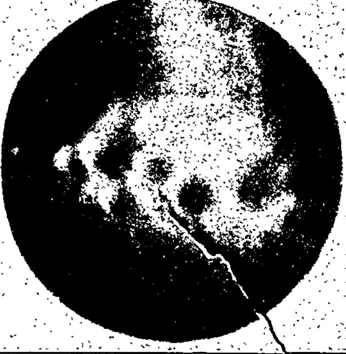
FIG. 6.—A gastro-enterostomy stoma just above and to the left of the centre of the picture. Above, and to the left again, a nodular appearance is seen. The interpretation is difficult. Comparing it with Fig. 5, the two are very similar, but here the reflected light is softer. Possibly the mucosa is swollen and nodular, more probably a plaque of mucus lie alongside the stoma, and with it bubbles of gas ar incorporated. The patient had a gastric ulcer (shown in Fig. 8, and also radiographically). When the photograph was taken it was known that an operation had been performed five years previously, but no until a photographic diagnosis had been made were the notes available, proving that a posterior gastro-enterostomy had been performed at another hospit for a perforated duodenal ulcer. (Magnificati unknown.)

FIG. 7.—Normal rugæ, with droplets of mucus to the right and below. Here the reflection of light is hard and brilliant. The rugæ cast definite shadow but the mucus casts none. From about 8 o'clock fold is seen passing upwards and to the right, dis appearing about 2 o'clock. About halfway it f the lateral soon fading away. Higher up, it forks, and both branches are visible as far as the of the picture. Other rugæ are less easily tinguished. (× 1⅓).

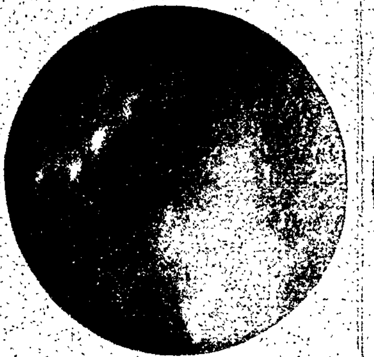
FIG. 8.—Ulcer on the posterior surface. The patient was the same as in Fig. 6. On two separate occasions the ulcer was demonstrated by X rays. It is situated on the posterior surface near to the lesser curvature. It is seen about 2 o'clock in the picture, and there is much mucous exudate round about it. (× 1⅓.)

FIG. 9.—An ulcer on the lesser curvature, surrounded by swollen, œdematous rugæ. Radiograms showed " a small ulcer on the lesser curvature." The

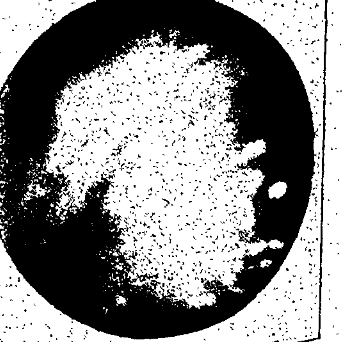
FIGS. 5



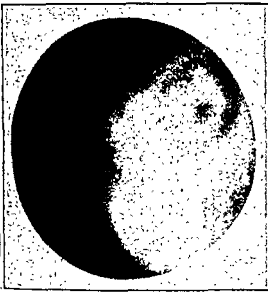
6



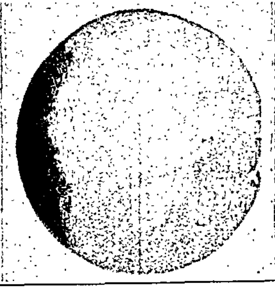
7



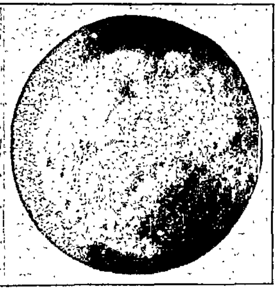
FIGS. 8



9



10.



lcer is situated on the lesser curvature, and is seen low and to the right. The mucosa above and to e left presents a rounded, nodular appearance. Magnification unknown.)

FIG. 10.—An ulcer with raised edge partly surounded by frothy mucus. The same patient as in ig. 5. The base is nodular. Below and to the left e wall overhangs and casts a shadow. A spur of wollen mucosa runs upwards and to the left in the wer part of the ulcer. Radiograms show a large, enetrating ulcer. (Magnification unknown.)

FIG. 11.—Two small polyps on the lesser curvature a patient suffering from epigastric pain, nausea, atulence, and loss of weight. Three years ago ll-stones were removed by operation. No radioaphic evidence of any gastric lesion. The polyps e seen as two small, papillary growths placed close ther where light and shadow meet to the left of picture. They have a dull matt surface, and w a shadow upwards. To the right of them ugae are seen. (× ⅓.)

FIG. 12.—Carcinoma of the pyloric end of the tomach. The nodular surface of the growth is vident, as is the curved edge rising from the mucosa longside. Radiograms showed a filling defect. At peration an inoperable cancer was found. (× ½.)

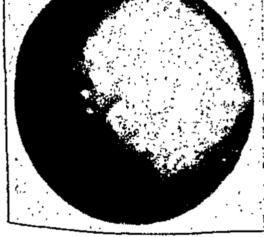
FIG. 13.—Partial gastrectomy performed six months previously. The scar is seen running from ight to left. On the extreme left the wall is in partial shadow, and a number of dark spots are visible. These are probably bubbles of gas in a layer of mucus. (× ⅓.)

As already explained, each film receives two separate images. If one pair of pin-holes lies close to the wall of the stomach the two pictures on the corresponding film will be totally different, representing separate and distinct portions of the gastric wall. If the holes be some distance from the stomach wall the two pictures on the corresponding film will be more or less identical, the similarity becoming greater the greater the distance between camera and stomach wall. A very simple apparatus has been devised whereby it is possible, if the two pictures are at all comparable, to measure the magnification reached. But if the two pictures are different, so that no point on the one corresponds with any point on the other, then no means of determining the magnification is known. Hence in some of the illustrations it is impossible to state the relationship in size between the picture and the part of the stomach wall represented. The less the distance between the camera and the stomach wall the greater the magnification in the final picture, so that those pictures of which the magnification is unknown are probably about, or larger than, natural size.

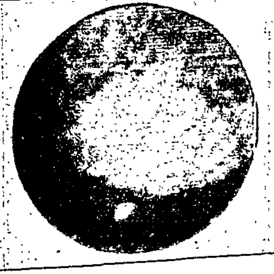
Comment.

I think that these illustrations are sufficient to show that lesions of the stomach can in fact be reproduced photographically, and that they warrant the hope that in the future the method will be found of definite clinical value. They are selected from the results of examining 31 patients. In none of these was the slightest difficulty experienced in introducing the instrument into the stomach, nor did the introduction

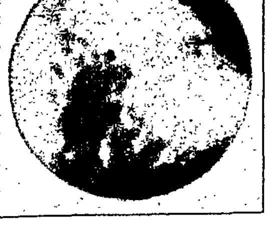
FIGS. 11



12



13.



occupy more than a few seconds. Several of the patients have subsequently been examined a second time. No patient has refused a second examination. One lady, not included in the above number, developed a spasmodic contraction of the pharyngeal constrictors immediately the camera reached the base of the tongue, so that although an attempt was made on two separate occasions to pass the instrument both attempts failed. This is the only failure up to the present.

It is a pleasure to record my great indebtedness to Mr. Leslie Smith, of the Radiological Department of the Cancer Hospital, for the time and labour he has devoted to the development and printing of the photographs. To obtain the best results a high degree of skill and experience are essential. I also thank Prof. J. M. Woodburn Morison, director of the department, for placing Mr. Smith at my disposal.

COMPLETE AND PARTIAL HEART-BLOCK DURING AN ATTACK OF RHEUMATIC FEVER.

By Maurice Campbell, M.D. Oxf., F.R.C.P. Lond.,
ASSISTANT PHYSICIAN, GUY'S HOSPITAL; AND PHYSICIAN TO OUT-PATIENTS, NATIONAL HOSPITAL FOR DISEASES OF THE HEART.

Delayed conduction down the auriculo-ventricular bundle, as shown by a lengthening of the P–R interval, is not very uncommon in the course of acute rheumatism; a higher degree of block, giving rise to dropped beats or 2 : 1 response, is less common, and complete heart-block is rare. The following patient is therefore of interest, especially because of her complete recovery.

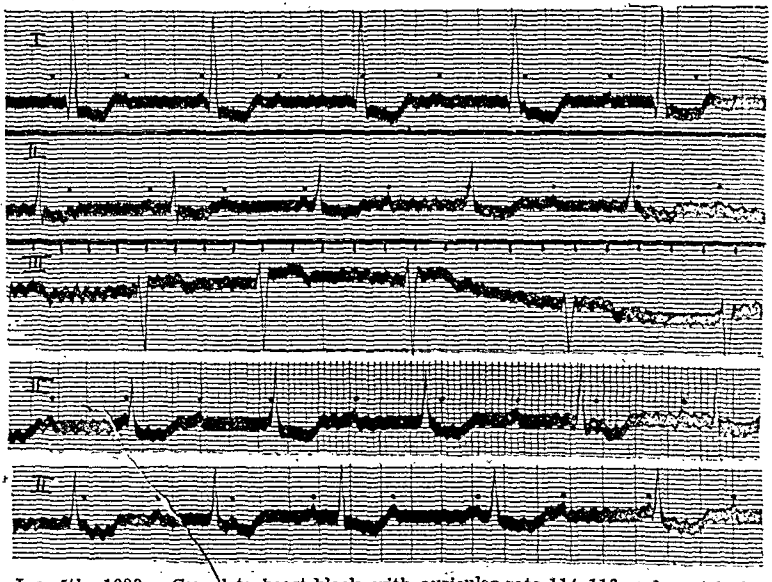
She had rheumatic fever when 12 and again when 14, and came under observation with her third attack in 1925, when 25 years old. Pyrexia persisted for ten days, and after three weeks there was still pain and swelling of the joints in spite of treatment with salicylates. The heart was enlarged to the left; in the aortic area there was a diastolic murmur which was conducted to the apex; there were no signs of mitral stenosis. Radioscopy showed enlargement to the left, typical of aortic disease, without any dilatation of the auricles or right-sided enlargement to suggest mitral stenosis. The average blood pressure was 125/60. She rested in hospital for six months. During the next three years she was able to do easy housework, and generally seemed rather better when taking tincture of digitalis, 30 minims daily.

On Dec. 16th, 1928, she was readmitted for pains in the joints; her temperature rose to 102° F. and her pulse-rate to 140. On the 21st her pulse was noticed to be slower and irregular; it felt like frequent dropped beats alternating with runs of extrasystoles, but actually these were the short periods when the ventricle was responding to each alternate beat, or to each beat of the rapid auricle. Since admission she had been taking daily 20 minims of tinct. digitalis, which was at once stopped and not again given. At the end of the month she seemed better, with no pyrexia and little pain; the pulse continued irregular.

On Jan. 1st, 1929, the pains returned and her temperature rose to 101°, but the pulse became more regular, the rate falling to 50–60. On the 5th, her temperature having fallen to normal, an electrocardiogram showed complete heart-block (Fig. 1) though the ventricular rate was about 60 and [illegible] little more than half the auricular rate. The joint pains persisted without further pyrexia till about the middle of the month. The Wassermann reaction was negative and there was nothing to suggest that she had suffered from a syphilitic infection.

On Jan. 11th, when the pulse had become faster and irregular, an electrocardiogram showed short runs of partial heart-block with the P–R interval lengthening until there was a dropped beat, followed by 2 : 1 heart-block for a few beats, when the [illegible] was repeated (Fig. 2)—e.g., in one case the [illegible] intervals in seconds were 0·16, 0·20, 0·20, 0·20, [illegible] no response, 0·16, no response, 0·16, &c. There was no significant change in the electrocardiogram on Jan. 21st and on Feb. 9th. The auricular rate was generally a little over 100 and the ventricular rate varied each few seconds from 50 to 100. On Feb. 28th the pulse-rate was regular, just over 60 with constant 2 : 1 block, which could hardly have been diagnosed even from the electrocardiogram except by comparison with previous and subsequent records. On March 3rd there was a slight return of pain and the temperature rose to 102°, but it fell to normal on the fourth day and there was no further pyrexia. In April she was allowed up on a couch, and in May went away to a convalescent home. Electrocardiograms in March and April still showed irregular 1 : 1 and 2 : 1 block, the auricular rate being about 100–120 and the ventricular rate about 70.

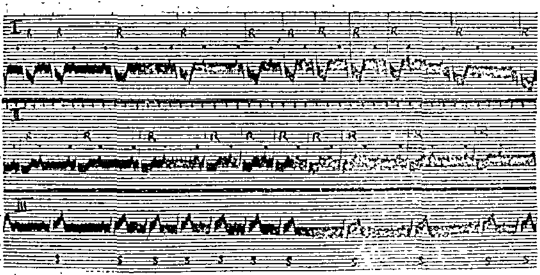
Fig. 1.



Jan. 5th, 1929. Complete heart-block, with auricular rate 114–116 and ventricular rate 62·5. Lead II. is here shown three times. In this and Fig. 2 the dots mark the auricular P waves. The time marker shows fifths and twenty-fifths seconds.

She returned home in July and was then able to walk to hospital. Rather to my surprise, all signs of block had disappeared and her

FIG. 2.



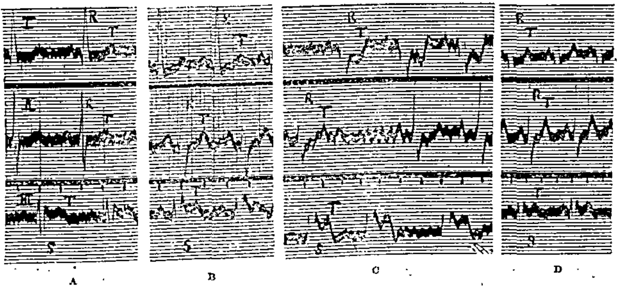
Jan. 11th. Short alternating runs of 1 : 1 and 2 : 1 heart-block—auricular rate 107. Note increasing length of P–R interval where there is 1 : 1 response, and inversion of T waves, completely in lead I. and partially in lead II.

condition seemed much the same as a year before (Fig. 3 D).

In addition to the changes in the P–R interval there were striking changes in the T waves which provided further evidence of myocarditis. Before this attack the T waves were just upright in lead I., upright in lead II., and atypical but upright in lead III. (Fig. 3 A and B). Apart from minor digitalis effects there had been no changes for two years. In January, 1929, when she had heart-block the T waves were deeply inverted in lead I., slightly inverted in lead II., and more upright but atypical in lead III. (Figs. 1 and 2). At the end of January T was partly upright in lead II. (Fig. 3 C); by February it was definitely upright, and T in lead I. was less inverted, being now biphasic. In April there had been no further change and T was still as much inverted in lead I., but in July and August there had been a complete return to the normal upright waves, just as before the attack (see Fig. 3 D). It is most usual for inversion to occur in lead I. where there is preponderance of the left ventricle, as there has been all the time in this patient. An orthodiagram taken in October, 1930, shows some enlargement of the heart to the left without evidence of mitral stenosis. There was no appreciable change from 1926.

The patient has since remained well and is now (May, 1931) able to do as much as before this attack of rheumatism. Frequent electrocardiograms since have always shown a normal P–R interval. She has, therefore, made a good recovery although complete heart-block was present for some days, and partial heart-block for some months, during and after her fourth attack of rheumatism. It is in accord with general experience that heart-block is more apt to occur in cases with disease of the aortic valve.

FIG. 3.



Electrocardiograms before, during, and after her fourth attack of rheumatic fever. (A) February, 1927, (B) February, 1928, (C) Jan. 21st, 1929, and (D) August 5th, 1929. Figs. 1–2 were obtained in the interval between (B) and (C). Note that the P–R interval in (D) is of normal length in spite of the presence of block previously. Note also the inversion of the T wave in lead I., with subsequent recovery (see text).

CLINICAL AND LABORATORY NOTES

APLASTIC ANÆMIA.

SEQUEL TO A CASE REPORT.

BY A. G. GIBSON, M.D. OXF., F.R.C.P. LOND.,
PHYSICIAN TO THE RADCLIFFE INFIRMARY, OXFORD.

THE case history of the patient with aplastic anæmia published in THE LANCET (1926, ii., 948) under the title of The Action of Adrenalin in Aplastic Anæmia aroused some interest, and it is important that the subsequent history should be put on record.

The patient was a girl of 11 who, in the spring of 1923, began to suffer from bruises in various parts of the body, for which no origin could be ascertained, and she was paler than normal. A diagnosis of aplastic anæmia was made. She was given seven transfusions during a period of 19 months and, from a time when she appeared almost certainly to be failing rapidly, with hæmorrhages in various parts of the body, daily injections of adrenalin produced an apparent and startling recovery. Her history was traced at that time for 16 months after the treatment with adrenalin had begun, during which time she had been able to take her part in ordinary life, though the blood count was persistently abnormal. The last blood count for which there were complete figures at that time, in July, 1926, showed 3,490,000 red cells, 72 per cent. of hæmoglobin, a colour-index to 0·95, and 4680 white cells. The differential count (per cent.) was: polymorphs, 32·5; small lymphocytes, 45·5; endothelials, 16·5; eosinophils, 0·5;

neutrophil myelocytes, 4·0; eosinophil myelocytes, 0·5; large lymphocytes, 0·5.

From the end of 1926 until her death on April 30th, 1931, she was continuously on adrenalin, with one brief interval. Her general appearance was that of a slightly built young woman with a just noticeable pallor, and a slight darkening of the skin of the face. Her weight, which was 6 st. 8 lb. in September, 1926, rose with slight intermissions up to 7 st. 1 lb. in February, 1931. She was fairly well nourished, and the skin, especially over the abdomen and to a lesser extent over the chest, presented a marked generalised pigmentation. Two deeper patches were present on the back, but they had been present before the illness. There was no pigmentation of the mouth nor any intense pigmentation of those parts subjected to slight irritation, such as the axillæ and waist. At no period was the pulse rapid, the blood pressure remained normal—about 120 maximum and 80 minimum—though on one occasion the maximum was 140. The heart was never found enlarged, and no murmurs were ever detected. The abdominal organs were also normal; neither liver nor spleen was enlarged during any occasion on which she was examined subsequent to 1926, and there was never anything abnormal in the urine. Menstruation had remained regular, though on occasions it was scanty and shorter than it had been.

On no occasion—except that to be referred to—was there any return to the hæmorrhagic condition from which she had previously suffered. "Bruises" were indeed occasionally noticed though, since she was an active person, a slight injury could not be excluded. Though for the most part she led an active existence in the country, and was able to walk and swim as well as other girls of her own age, she could not stand the burden of a post in London with light duties which she tried to take up. She never appeared fatigued, and was never unusually breathless when at home.

In March, 1930, her condition was more or less stationary; she was in good health, apart from the anæmia, and it was thought desirable to give up adrenalin in order to see whether she could do without it. After 12 days she had two slight nose-bleedings, and a third subsequently, much slighter, after the adrenalin was resumed. The opinion of her parents was that it was not wise to give up the adrenalin. She had not, however, felt unwell as a result of leaving it off.

She had occasional colds. In 1929 she suffered from an attack of diarrhœa and was two days in bed, and it was not generally thought that she had any specially lowered resistance to intercurrent febrile disease. In the last four days of April, 1931, however, she contracted chicken-pox from another person, and the rash, which was typical in distribution and character, on the third day became hæmorrhagic. There were sores round the mouth, extreme fœtor of the breath, with gangrene of the gums, and dysphagia set in 18 hours before death. Hæmorrhage occurred from the bowel, and there was some blood in the urine. She relapsed into a muttering delirium. Two gangrenous patches appeared on the back. Before this, however, there had been several attacks of excruciating pain in the back, requiring morphia. This pain was not located to any function, and its anatomical origin could not be determined. She died on the fourth day of the disease.

The condition of the blood had remained practically at the level that was reported before. In all, 25 blood counts were taken between September, 1926, and February, 1931. The average of these is as follows: red cells, 3,020,000; hæmoglobin, 64 per cent.; colour index, 1·6; white cells, 2700. Differential count: polymorphs, 27 per cent.; lymphocytes, 56·7 per cent. Taking the hæmoglobin as an indication of the anæmia, there was a tendency to fall as time went on. The average hæmoglobin of the year's counts is as follows: 1927, 60 per cent.; 1928, 50 per cent.; 1929, 66 per cent.; and 1930, 58 per cent. The last hæmoglobin percentage recorded was 56 per cent. The halometer reading (Eve), which is an indication of the size of the corpuscles, showed no significant variation from the normal. Microscopically there was usually some evidence of activity of the bone-marrow in the presence of anisocytosis and polychromasia. Now and then immature cells, such as neutrophil myelocytes and large lymphocytes, were present in the differential counts. Platelets were usually present, but in small numbers (not counted).

Numerous attempts have been made to ascertain the causation of the anæmia, both from the history and by giving drugs. Her residence in India, and indeed the diagnosis of malaria made in that country, appeared to suggest that disease as the initial cause. Treatment by quinine, however, has never made any difference that could be estimated, and there have been no attacks of fever such as could be attributed to that agent.

The conclusion appears to be that, through some unknown cause, the blood-forming organs had been partly destroyed, leaving the patient with sufficient for a modified existence when constantly stimulated by adrenalin, but that, without the adrenalin, the bone-marrow activity was insufficient to prevent the tendency to hæmorrhage. During the greater part of her life, since the adrenalin was started, there was no special lack of resistance to infections, but this lack of resistance was unmasked or induced by the attack of chicken-pox which brought back the hæmorrhagic tendency in its former violence.

TREATMENT OF HABITUAL ABORTION WITH WHEAT-GERM OIL (VITAMIN E).

By P. Vogt-Möller, M.D.

(*From the County and City Hospital, Odense, Denmark*)

The existence of a fat-soluble antisterility vitamin—vitamin E—must now be considered established. Papers on this vitamin up to the year 1927 are reviewed in Evans and Burr's monograph[1]; I would, however, mention here that the first information about such a vitamin is due to Evans and Bishop.[2]

Vitamin E is found in certain vegetable oils, chiefly in wheat-germ oil, but also in many other oils of vegetable origin. Sure,[3] for instance, found it in crude maize oil but not in the commercial product of maize oil; it is also to be found in plant leaves—e.g., of lettuce. Little or no vitamin E is found in animal substances; it is, for instance, not found in cod-liver oil.

As yet the importance of vitamin E to the organism has only been elucidated in detail for rats. Beard,[4] however, has proved that mice, too, need vitamin E. The sterility occurring when this vitamin is lacking in the food is of a different pathogenesis in the two sexes. In the male the vitamin seems to play a part in spermatogenesis, histological changes of the testes being found in avitaminosis E, especially a more or less marked degeneration or even complete disappearance of the spermatogonia. In the female, on food free from vitamin E, ovulation and implantation take place normally, the reproductive system being unimpaired, and the sterility being due to the fact that the implanted ova are resorbed at an early stage of the pregnancy. In male as well as in female animals vitamin E may be stored to a certain extent.

In 1927 Evans and Burr[5] [6] showed that various fats—e.g., lard—when mixed with vitamin E (wheat germ or wheat-germ oil) were capable of depriving the latter of its value as a vitamin; this vitamin-destroying property of the fat increased with its rancidity, and Evans and Burr[7] drew attention to "the possibility of destroying vitamin E by the development of rancid substance in wheat-germ oil itself," and calls to the importance of using fresh preparations. Without going into further detail as far as researches of recent years are concerned, I need only refer to McCollum and Simmonds's[8] and Jackson's[9] monographs, and to Cummings and Mattill's[10] work.

The preparation used as the source of vitamin E in the cases mentioned below was wheat-germ oil; by the courtesy of Miss M. H. Roscoe, of the Lister Institute, London, the wheat germs used—a very pure preparation—were delivered by Messrs. I. and H. Robinson, Ltd., Deptford Bridge Mills, London, and the wheat-germ oil was made from the germ in the manner described by Vogt-Möller and Bay,[11] [12] and Vogt-Möller.[13] According to Evans,[14] wheat-germ oil only contains minimal amounts of vitamin A.

The dose of wheat-germ oil necessary for rats is only a few drops daily, and, according to Evans and Burr,[1] vitamin E (wheat-germ oil) is efficacious both on enteral and parenteral application. That wheat contains toxic elements when extracted in ether, as was maintained by Hart, Miller, and McCollum,[15] and by Hart, McCollum, Steenbock, and Humphrey,[16] has been thoroughly refuted by Osborne and Mendel,[17] and all researches of recent years.

As I had worked for years on the question of vitamin E and reproduction in small experimental animals (rats and mice) without reaching any essentially new conclusion, but confirming Evans and Burr's investigations in every respect, it was natural for me to try its effects in veterinary medicine. Vogt-Möller and Bay[11] [12] obtained favourable results in the treatment of sterility in cows with wheat-germ [illegible]; from this treatment to the treatment of habitual abortion in women there was only one step. Since treatment with cod-liver oil, as suggested by Poulsson,[18] and with Vigantol, as recommended by Novak,[19] had to be considered as contraindicated from an experimental point of view in habitual abortion, cod-liver oil being capable of causing abortion in rats when administered in excess (as shown by Hartwell[20] and Sure[21]), I tried wheat-germ oil, which in both cases led to the desired result—viz., a pregnancy with a normal course and a healthy viable child.

CASE 1.—The patient was a married woman, aged 24, who, apart from the ordinary diseases of childhood, had always been in good health and had menstruated normally since her thirteenth year. Both she and her husband were healthy and sound, and in both of them the Wassermann test was negative. The patient had aborted four times after absence of menstruation for seven to eight weeks. She came under treatment six weeks after the last menstruation, and on examination an enlarged—and in all probability pregnant—uterus was found, but otherwise nothing abnormal. The diagnosis of pregnancy having been further substantiated by a positive Zondek-Aschheim reaction, a treatment with wheat-germ oil by mouth was instituted, 5 c.cm. being given once a day during the first fortnight, then 5 c.cm. every second day for the next fortnight, and then 5 c.cm. every sixth day. Throughout the pregnancy the patient was quite well, and at term she was delivered of a healthy girl, weighing 3260 g., who is doing well. The placenta was of normal appearance. The treatment with wheat-germ oil did not cause any inconvenience.

CASE 2.—The patient, aged 20, had been married for six years. She had had the ordinary children's diseases and had menstruated regularly since her fourteenth year. At the age of 16 she had had acute appendicitis, and an appendicectomy had been performed. At the age of 25 she passed through a normal labour; the child, a boy weighing 3400 g., is in good health. The patient then became pregnant five times, but aborted each time in the third or fourth month. The abortions were quite spontaneous each time, no interference being made. Both the patient and her husband were healthy, and the Wassermann test was negative in both. During the last pregnancy when the patient came under treatment in the seventh week, a course of treatment with wheat-germ oil, consisting of 5 c.cm. by mouth daily for a fortnight, was instituted; then 5 c.cm. was administered every sixth day during the remaining period of the pregnancy. The patient showed a good toleration to the treatment, and at term a healthy girl weighing 2900 g. was born; the child is in good health.

The diet of these two patients did not deviate from the ordinary food taken in Denmark; it can hardly have been poor in vitamin E, but possibly the need for this vitamin varies in different individuals, so that a hypovitaminosis E may have been present in the above cases. The material, however, is too scanty to allow us to base anything decisive on it, but nevertheless it will presumably be inferred that vitamin E preparations may be of therapeutic value in the treatment of habitual abortion in women.

A CASE OF XEROSTOMA AND XEROPHTHALMUS.

By JAMES L. O. TILLEY, M.R.C.S., L.D.S.R.C.S. ENG.

A MARRIED woman, aged 34, with no children and a good family history, had suffered during childhood from epistaxis and "nervous coryza" and at the age of 15 from profuse sweats, which were particularly associated with mental agitation. At the age of 21 she had had diphtheria, followed by paresis of the soft palate. For these complaints she had received X rays (for the sweats) and cauterisation of the nose (for the epistaxis and nervous coryza). The treatment was stated to have been beneficial. Her general physical condition was normal. She was highly strung but there were no symptoms of neurasthenia or hypochondria.

On June 29th, 1925, the patient was subjected to severe mental agitation and strain. A fortnight later, whilst driving to her home, she suddenly became aware that she was unable to articulate and could only swallow with difficulty until she was able to moisten her mouth and throat with water. At this time she "suffered great mental agony." This neutrophil myelocytes, 4·0; eosinophil myelocytes, 0·5; large lymphocytes, 0·5.

From the end of 1926 until her death on April 30th, 1931, she was continuously on adrenalin, with one brief interval. Her general appearance was that of a slightly built young woman with a just noticeable pallor, and a slight darkening of the skin of the face. Her weight, which was 6 st. 8 lb. in September, 1926, rose with slight intermissions up to 7 st. 1 lb. in February, 1931. She was fairly well nourished, and the skin, especially over the abdomen and to a lesser extent over the chest, presented a marked generalised pigmentation. Two deeper patches were present on the back, but they had been present before the illness. There was no pigmentation of the mouth nor any intense pigmentation of those parts subjected to slight irritation, such as the axillæ and waist. At no period was the pulse rapid, the blood pressure remained normal—about 120 maximum and 80 minimum—though on one occasion the maximum was 140. The heart was never found enlarged, and no murmurs were ever detected. The abdominal organs were also normal; neither liver nor spleen was enlarged during any occasion on which she was examined subsequent to 1926, and there was never anything abnormal in the urine. Menstruation had remained regular, though on occasions it was scanty and shorter than it had been.

On no occasion—except that to be referred to—was there any return to the hæmorrhagic condition from which she had previously suffered. "Bruises" were indeed occasionally noticed though, since she was an active person, a slight injury could not be excluded. Though for the most part she led an active existence in the country, and was able to walk and swim as well as other girls of her own age, she could not stand the burden of a post in London with light duties which she tried to take up. She never appeared fatigued, and was never unusually breathless when at home.

In March, 1930, her condition was more or less stationary; she was in good health, apart from the anæmia, and it was thought desirable to give up adrenalin in order to see whether she could do without it. After 12 days she had two slight nose-bleedings, and a third subsequently, much slighter, after the adrenalin was resumed. The opinion of her parents was that it was not wise to give up the adrenalin. She had not, however, felt unwell as a result of leaving it off.

She had occasional colds. In 1929 she suffered from an attack of diarrhœa and was two days in bed, and it was not generally thought that she had any specially lowered resistance to intercurrent febrile disease. In the last four days of April, 1931, however, she contracted chicken-pox from another person, and the rash, which was typical in distribution and character, on the third day became hæmorrhagic. There were sores round the mouth, extreme fœtor of the breath, with gangrene of the gums, and dysphagia set in 18 hours before death. Hæmorrhage occurred from the bowel, and there was some blood in the urine. She relapsed into a muttering delirium. Two gangrenous patches appeared on the back. Before this, however, there had been several attacks of excruciating pain in the back, requiring morphia. This pain was not located to any function, and its anatomical origin could not be determined. She died on the fourth day of the disease.

The condition of the blood had remained practically at the level that was reported before. In all, 25 blood counts were taken between September, 1926, and February, 1931. The average of these is as follows: red cells, 3,020,000; hæmoglobin, 64 per cent.; colour index, 1·6; white cells, 2700. Differential count: polymorphs, 27 per cent.; lymphocytes, 56·7 per cent. Taking the hæmoglobin as an indication of the anæmia, there was a tendency to fall as time went on. The average hæmoglobin of the year's counts is as follows: 1927, 69 per cent.; 1928, 59 per cent.; 1929, 66 per cent.; and 1930, 58 per cent. The last hæmoglobin percentage recorded was 56 per cent. The halometer reading (Eve), which is an indication of the size of the corpuscles, showed no significant variation from the normal. Microscopically there was usually some evidence of activity of the bone-marrow in the presence of anisocytosis and polychromasia. Now and then immature cells, such as neutrophil myelocytes and large lymphocytes, were present in the differential counts. Platelets were usually present, but in small numbers (not counted).

Numerous attempts have been made to ascertain the causation of the anæmia, both from the history and by giving drugs. Her residence in India, and indeed the diagnosis of malaria made in that country, appeared to suggest that disease as the initial cause. Treatment by quinine, however, has never made any difference that could be estimated, and there have been no attacks of fever such as could be attributed to that agent.

The conclusion appears to be that, through some unknown cause, the blood-forming organs had been partly destroyed, leaving the patient with sufficient for a modified existence when constantly stimulated by adrenalin, but that, without the adrenalin, the bone-marrow activity was insufficient to prevent the tendency to hæmorrhage. During the greater part of her life, since the adrenalin was started, there was no special lack of resistance to infections, but this lack of resistance was unmasked or induced by the attack of chicken-pox which brought back the hæmorrhagic tendency in its former violence.

TREATMENT OF HABITUAL ABORTIO WITH WHEAT-GERM OIL (VITAMIN E).

By P. Vogt-Möller, M.D.

(From the County and City Hospital, Odense, Denma

The existence of a fat-soluble antisterility vita —vitamin E—must now be considered establish Papers on this vitamin up to the year 1927 reviewed in Evans and Burr's monograph[1]; I woul however, mention here that the first informatio about such a vitamin is due to Evans and Bishop.[2]

Vitamin E is found in certain vegetable oils, chiefl in wheat-germ oil, but also in many other oils o vegetable origin. Sure,[3] for instance, found it in crude maize oil but not in the commercial product of maize oil; it is also to be found in plant leaves—e.g., of lettuce. Little or no vitamin E is found in animal substances; it is, for instance, not found in cod-liver oil.

As yet the importance of vitamin E to the organism has only been elucidated in detail for rats. Beard,[4] however, has proved that mice, too, need vitamin E. The sterility occurring when this vitamin is lacking in the food is of a different pathogenesis in the two sexes. In the male the vitamin seems to play a part in spermatogenesis, histological changes of the testes being found in avitaminosis E, especially a more or less marked degeneration or even complete disappearance of the spermatogonia. In the female, on food free from vitamin E, ovulation and implantation take place normally, the reproductive system being unimpaired, and the sterility being due to the fact that the implanted ova are resorbed at an early stage of the pregnancy. In male as well as in female animals vitamin E may be stored to a certain extent.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING IN EASTBOURNE.

PROCEEDINGS OF THE REPRESENTATIVE BODY.

THE annual Representative Meeting of the British Medical Association opened at the Town Hall, Eastbourne, on July 17th, with Dr. C. O. HAWTHORNE in the chair. Lord DAWSON OF PENN was elected President of the Association for 1932–33.

Antenatal Clinics.

Dr. B. H. PAIN, for Tunbridge Wells, moved that the Council should consider and report on the various antenatal schemes now being administered in different parts of the country without waiting until the Government maternity scheme was published. A year ago, he said, Dr. Brackenbury had stated that the Ministry of Health regarded the B.M.A. scheme for a national maternity service not unfavourably, but no Parliamentary Bill appeared to have been drafted embodying the principles of that scheme. In the meantime antenatal clinics in charge of whole-time medical officers were increasing throughout the country and patients were being examined by doctors who would never attend them in their confinements. To begin a maternity service on different lines from those laid down by the B.M.A. was to consolidate it on different lines. It was not the business of the local branches and divisions to oppose such developments in their own areas, but rather a matter for central opposition from the Council. In Kent, for example, the medical officer of health agreed with the policy laid down in the Association's scheme, but he had no influence with the 20 or 30 local authorities who were providing antenatal clinics with full-time medical officers.—Dr. H. B. BRACKENBURY (chairman of Council) said he was prepared to accept the motion of Tunbridge Wells, but he thought there were limits to the influence which could be exerted by the Council on local developments. It was not possible to insist that the proposals made to the Ministry of Health should be put into action. The Council could only rest in the assurance that the Ministry was actively in favour of a scheme following some of the lines laid down by the Representative Meeting. A circular had been issued to local authorities in which emphasis had been laid on the value of the general practitioner in local maternity schemes. The divisions and branches of the Association should see that this recommendation of the Ministry was carried out.

The meeting supported the proposal of Tunbridge Wells.

Medical Patents.

Dr. ARNOLD LYNDON (chairman of the Central Ethical Committee) introduced the question of patents. The proposal he brought forward was that the Association, while adhering to the traditional view that it is unethical for a medical practitioner who discovers or invents any substance, process, apparatus, or principle likely to be of therapeutic value, to act against the public interest by unduly restricting its use for his own personal advantage, should nevertheless recognise the propriety of utilising arrangements made by law for the protection of such inventions or discoveries and the reward of those who have made them, provided the principles enunciated above were duly safeguarded. Last year the question of dedicated patents had arisen and the whole subject, said Dr. Lyndon, had been referred back to the Council for further consideration, but in the last few months the Board of Trade Patents Committee had reported unfavourably on dedicated patents, so that these need no longer be regarded as coming in the realm of practical politics. Foreign countries at present held an advantage in that an English invention might be published and foreign competitors might patent it, thus keeping the inventor from using his own discovery. The value of the Patent Laws was to promote industrial activity. If after four years there was found to be abuse of a patent the controller could investigate the position and revise or withdraw that patent. Since the above motion was drafted, Dr. H. H. Dale had set out the point of view of workers in laboratories where medical research was carried on (*British Medical Journal*, June 27th, Supplement). Dr. Dale found that far from resenting the embargo on patents in medical research these workers regarded it as a charter of liberty and open dealing. He doubted, moreover, whether it was possible to give a fair definition of "unduly restricting" and he thought it would be far wiser to repeal all references to patents from the policy of the Association and to regard the subject as outside its province. Dr. Lyndon thought that some of the dangers foreseen by Dr. Dale would not occur. He pointed out that a patent could not be obtained without full disclosure of the details of the process or invention and, far from leading to secrecy, it brought any discovery that was made into the open.

Dr. J. S. MANSON spoke in support of Dr. Dale's letter. The meeting must consider whether Dr. Lyndon's motion opened the door to the commercialisation of medical invention and discovery. Patenting was permitted to medical men in other countries. He thought that considerable weight must be given to Dr. Dale's letter and he suggested that the subject might be referred for discussion by the Association Professionnelle Internationale des Médécins.—Dr. J. W. BONE and Dr. LYNDON thought that it was undesirable to go abroad for an opinion and that it was the business of the Representative Meeting to express their own view of the position.—Sir ROBERT BOLAM persuaded Dr. Manson to withdraw his suggestion and Dr. R. D. MOTHERSOLE introduced an amendment limiting the application of the motion to those engaged in scientific research. It was felt, however, that this amendment unduly restricted discussion and it was not accepted by the meeting. Sir ROBERT BOLAM then proposed another form of the motion to read as follows:—

> "That the Association approves the traditional professional usage in accordance with which it is unethical for any medical practitioner who discovers or invents any substance, process, apparatus, or principle likely to be of value in the treatment of patients to act against the public interest by unduly restricting, by patent or otherwise, the use and knowledge of such discovery or invention for his own personal advantage."

This, he said, would not interfere with the action of any person who thought he ought to take out a patent if he felt he could do so without disadvantage to the public. It also left the field clear for those who did not wish to take out patents.

Mr. H. S. SOUTTAR appealed to the meeting to adhere to the original motion. The present attitude of the Association placed the medical man in an invidious position and made him feel he was doing something wrong when he wished to take out a patent, whereas really he would probably be performing an act of value to his country and to national industry. Foreign countries were able, at present, to reap the reward of British inventions and discoveries. If the proper patents had been taken out at the time, we should have kept the aniline dye industry in this incident coincided with the commencement of a gradual decrease in the amount of saliva and with a feeling of "dryness in the nose." A year later she suffered from severe paroxysms of headache which lasted for three days, and were followed by a decrease of the lacrymal secretions. Eighteen months after the initial shock (Dec., 1926) there was a complete cessation of all normal secretions from the eye, nose, and mouth, but during that period and up to the time of examination, she had secreted thick sebaceous material from the Meibomian glands and mucus from the nose, while on rare occasions globules of mucus had appeared in the mouth.

The symptoms of which the patient complained and the associated pathological conditions of the three organs, eyes, nose, and mouth, were as follows:—

Eyes.—Vision and pupil reflexes normal. There is a complete absence of moisture on the eyeball and, however strong the emotion or local irritation, there is no lacrymal secretion. A constant accumulation of thick sebaceous material from the Meibomian glands covers the eyeballs and is most marked on waking or when the patient is worried or mentally agitated. The irritation which results from this secretion necessitates frequent efforts on the part of the patient to remove it. Collosol argentum has given some relief while other applications seem to aggravate the discomfort. Whether the Meibomian secretions are abnormally copious and tenacious or only seemingly so (due to the absence of secretions from the lacrymal and Krause's glands), it is difficult to determine. On eversion of the upper eyelid the inferior lacrymal gland is seen to be to some extent atrophied, but the outlines of the Meibomian glands are well marked. There is some occlusion of the puncta lacrymalia and I have had difficulty in passing a sound.

Nose.—The sense of smell is good. The patient is able to sneeze but no liquid secretion is exuded. Every morning there is a large accumulation of mucus which adheres to the back of the soft palate and has to be removed by a nasal douche before the patient can breathe or articulate in comfort. She finds vaseline, applied inside her nostrils, gives relief from the dryness.

The nasal mucous membrane is normal in appearance but without the normal moisture. The patient has not suffered from colds or nasal catarrh since the commencement of her complaint.

Mouth.—The sense of taste is normal. There is a complete absence of salivary and buccal liquid secretion. The mucous membrane of the cheek, palate, and gums is smooth, shiny, and dry. The teeth show a marked tendency to decay. There is slight chronic superficial glossitis. Mastication, deglutition, and articulation are difficult and nearly impossible unless the patient first moistens her mouth.

The plicæ sublingualis are somewhat atrophied. The orifices of both Stenson's and Wharton's ducts are much contracted, and it has been found impossible to detect the orifices of the left upper Stenson's duct even when using a magnifying glass; but a strand of silkworm gut has been passed through both Wharton's ducts and the right Stenson's duct. After massaging the submaxillary region, while the patient exerted suction at the same time, two or three globules of mucus were occasionally seen around the orifices of Wharton's ducts. Galvanism has been applied to the chorda tympani nerve but without effect. Salivation takes place after the injection of pilocarpine, and also occurred during an attack of acute toothache lasting for three hours in 1930.

Food.—The patient can take any food except that of an acid or astringent nature, and she states she has "the digestion of an ox." The absence of ptyalin has been compensated for by the development of a desire to take large ,a' 1ntities of sugar, and she swallows about 15 from the 'umps" of sugar daily.

urine. She of smell, taste, and sight are in no way gangrenous ps the digestion. The dryness and local this, however, e parts affected, particularly the eye, excruciating pai in masticating and talking, are the This pain was ncomplained of. The mucus and anatomical origin em to function normally; the died on the fourth daose secreting liquid secretion.

The condition of the n function is shown by the at the level that was rencarpine, and that the whole counts were taken between ct, if only as a result of 1931. The average of these is by her salivating as a hæmoglobin, 64 per cent; c result of pain and to a lesser degree by the effect of pilocarpine.

Her symptoms seem to result from some derangement or disharmony of her sympathetic (autonomic) system. The most likely explanation of the cause and of its consequent symptoms appear to me to be as follows:—

1. That there has been a desensitising of some part of her reflex arc, with the result that only strong stimuli effect reflex action.

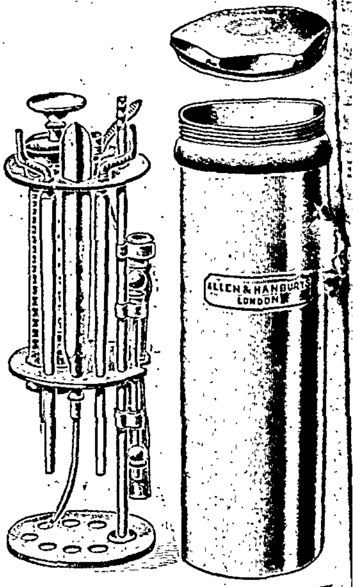
2. That the inhibition centres and perhaps the cortical connexions, either sympathetic or parasympathetic—it seems impossible to determine which—have become permanently excited by the residual effect of the initial shock.

The patient has unfortunately been unable to take complete rest or a holiday since the onset of the symptoms. Many drugs have been tried but none has been of any benefit. The treatment has resolved itself, during the last month, into repeated injections of pilocarpine, by which I hope to overcome the diminished sensitivity of the reflexes in question to normal stimuli; and there is no doubt that of late there has been more lacrymose secretion and that the nose is less dry.

NEW INVENTIONS

SPIRIT-PROOF CASE.

THE difficulty of sterilisation of the maxillary antrum puncture outfit and paracentesis knives before use has been met by the spirit-proof case here illustrated. The antral puncture outfit is the one designed by Mr. Cokeley, and all the instruments are of stainless steel.



Messrs. Allen & Hanburys, Ltd., Bethnal Green, London, E.C.2, are the makers.

ALFRED WALFORD,
F.R.C.S.

MANCHESTER HOSPITALS.—The foundation-stones were laid recently of the new Christie Cancer Hospital and the Holt Radium Institute at Withington. The cost, including the nurses' home, will be £150,000. The new hospital will have 104 beds instead of the present 33; last year there were 450 in-patients. The ceremony marked the physical union of two institutions which in separate buildings have for some years carried on work which has lately become so closely related that the boards of management have just been amalgamated under the chairmanship of Mr. Nathan.—Large additions to Ancoats Hospital have just begun. The new buildings will include a ward block four storeys high, having 15 beds on each floor, another block consisting of a massage department, a pathological department, and two theatres. Had sufficient money been forthcoming a further ward block with 60 beds and quarters for the additional nurses, together with more spacious domestic accommodation, would have been provided. As it is, the work now begun will cost £65,000, of which £45,000 is at present in hand.

police sent for the doctor in case of accident. He had found that out of 61 police forces in the country only 29 had agreed to this arrangement. The Medico-Political Committee had pointed out when the Road Traffic Act was before Parliament that the doctor should receive a fee as well as the hospital, but they had been told the doctor was in a position to sue for his fees while the hospital was not. He thought the best plan would be to take up the matter locally and to try to get the police forces to agree to pay a fee when they were responsible for calling a doctor. In other cases the local authority should be persuaded to pay a fee, if possible; in his district the local authority had agreed to pay the doctor's fee in all road accidents except those occurring to insured persons.

Dr. BONE admitted that he had acquired more constructive proposals from the discussion than he had anticipated. Dr. Fothergill had forgotten to point out that in Brighton an effective scheme was in force by which every policeman carried a voucher which is handed to the doctor; on presentation of this voucher the Brighton town council paid the fee. He believed there were similar schemes in operation in Willesden and Gateshead. The branches and divisions of the Association should try to induce their local authorities to adopt some plan of the kind.

Dr. Fothergill's proposal was adopted without contrary vote by the meeting.

Additional Benefits and Approved Societies.

Dr. DAIN (chairman of the Insurance Acts Committee) moved a resolution that the Association would deprecate medical practitioners taking service under any scheme for the provision of additional treatment benefits which would bring them directly or indirectly under the control of approved societies. This attitude with regard to the approved societies, he said, was one of the cardinal principles enunciated by the Association in 1911 and 1912. Additional treatment benefits had varied under the different insurance societies, depending on the surplus which each possessed, and had so far taken the form of a sum of money given to the patient for the necessary treatment; but it was not to the advantage of either the patient or the doctor that in any organised scheme for the provision of additional benefits the approved societies should have complete control.—In this view the meeting supported him with the alteration proposed by Hampstead, that "would deprecate" should be replaced by "disapproves of."

Two other motions introduced by Dr. DAIN were carried without discussion. The first related to additional treatment benefits 8 and 16, and proposed that services of a specialist or consultant nature should be given, so far as was consistent with the best interests of the patient, by a private practitioner at his consulting rooms, the patient's own home, or at clinics specially established for the purpose. The second provided that under additional benefit 10, where the patient was referred to hospital for treatment, the choice of hospital should lie with the doctor and patient, and not with the approved societies.

Choice and Change of Doctor.

Dr. DAIN said that the Association still objected to the new arrangements for change of doctor. At present the patient could only change his doctor once a quarter, and then only on giving a month's notice. This was against the principle of free choice, as well as being against the best interests of the patient. A number of difficulties were already arising; although the patient could, with the consent of both doctors, change at a moment's notice, he was usually loath to ask the practitioner with whom he was dissatisfied to sign the necessary paper, and as things stood he might be compelled to pay fees to the new doctor of his choice for three months before he could obtain a transfer. The patient was entitled to free treatment, and panel practitioners were prepared to give it, but this regulation could rule the patient out of the right to receive service for three months.

Dr. A. B. MURRAY (Banff, Moray and Nairn), introduced a resolution protesting against any interference with the liberty of the insured person to change his doctor when he so desired. The Association had always held the free choice of doctor to be a cardinal point in their policy. He mentioned a case in which the patient had wished to change his doctor one month before the quarter, but had been too late to give in his notice. As a result he had to pay fees for four months before he could change.—Dr. BRACKENBURY seconded the amendment. If the approved societies and the Ministry of Health were not going to support this cardinal principle the only remedy for the profession was to seek the weight of public opinion. The insured patient should be as far as possible in exactly the same position as the private patient. Approved societies in the interests of finance had curbed the freedom with which the insured person could change his doctor. It was a serious inroad on the rights of the patient. The opposition which the Association had always given to such limitation of freedom was in the interests, not of the doctor, but of the patient. The present system gave the doctor a vested right in the patient for a given period and this was wholly undesirable.—Dr. FOTHERGILL assured the meeting that in East Sussex and Brighton these draft regulations had been completely ignored. They had been promulgated in February but had never been confirmed.

Some opposition to the amendment was introduced by Dr. J. FORRESTER. He was somewhat embittered in the view he took of the case owing to an encounter with a patient who had changed his panel doctor five times in fourteen days.—He was supported by Dr. G. F. P. GIBBONS, who thought a sentimental attitude had been allowed to creep in with regard to the unfettered choice of doctor by the patient. In times of industrial depression patients were apt to "go sick" with undue frequency, and if they could not obtain certificates from their own practitioners they would go to less scrupulous doctors while they were in a position to transfer as frequently as they pleased.—Dr. D. F. TODD and Dr. R. D. MOTHERSOLE shared this view.—Dr. F. J. KERR thought that on this question the Association had an excellent opportunity to defy the Ministry in the interests of the patient.—Dr. E. STUNGO (Lambeth) put the position for free choice neatly. If the patient was genuinely dissatisfied he surely had a perfect right to change his doctor at once; if he was one of the disgruntled type who had no faith in any doctor, his practitioner would be only too glad to get rid of him.

Dr. DAIN considered that the present position *did not* actually abuse the principle of free choice; it had merely reduced considerably the opportunities for employing it. He did not think, however, that a crusade in which all insurance practitioners should go to the length of resigning in order to enforce the principle was appropriate or necessary at the present time.

Dr. Murray's resolution was carried.

Dividends and Gifts from Pharmacists.

Mr. F. C. Pybus, for Newcastle-on-Tyne, moved that the meeting was strongly opposed to the offer of any reward or dividend by chemists, as an inducement to an insured person to bring his prescriptions to be dispensed. In his district, he said, there was a tendency for insurance patients to have their prescriptions made up at the coöperative chemists rather than at the private chemists.—Dr. R. Boyd (Manchester) had also found that where the coöperative system was in operation the number of attendances at the surgery and the number of evening calls increased. The chemists had offered dividends to the patients in the form of cash, soap, and other commodities, to the detriment of both the drug fund and the general practitioner. It was not so long since medical attendance was given away with a pound of tea, and a time might yet come when patients would collect their panel prescriptions—50 for a gramophone, 100 for a wireless set.—Dr. Dain said that it was not legal for chemists to give bonuses, but that the position was the responsibility of the pharmacists and had nothing to do with the Association. The insurance committees were beginning to say that any bonuses which were given should belong to them.

The motion was carried without dissent.

Ophthalmic Service.

Mr. Bishop Harman said that it was within the knowledge of the Council that a few ophthalmic surgeons had been giving lectures to meetings of sight-testing opticians' organisations. The Association had always held the view that sight-testing by other than qualified medical practitioners was not in the best interests of the patient, and he therefore moved that a registered medical practitioner should not take part in the instruction or examination of opticians or student-opticians in clinical ophthalmology.—Dr. F. A. Roper thought the motion liable to misconstruction. Science was universal, and any refusal to disseminate knowledge should be preceded by an explanatory phrase. He suggested that the motion should state that, in view of the opinion of the Association that the practice of sight-testing by other than qualified medical practitioners was not in the best interests of the public, the Association considered that a registered medical practitioner should take no part in the instruction or examination of opticians or student-opticians in clinical ophthalmology.—This expression of opinion was supported by the meeting.

Mr. Bishop Harman gave a brief history of the National Ophthalmic Treatment Board scheme, which has now been running for two and a half years. Clinics, he said, were now held in a large number of towns in England and a few in Scotland and Wales. Those eligible for treatment were insured persons and their dependents and those families with an income of less than £250 per annum; a fee of 10*s.* 6*d.* was charged by the ophthalmic surgeon visited, and for this sum he gave all the advice possible at the first consultation. Although the scheme was still run at a loss there was every hope that it would be self-supporting next year.—Certain speakers, including Dr. Campbell Orr, spoke in favour of the scheme, but a motion was introduced by Dr. E. E. Brierley, for Cardiff, that the general practitioner should be allowed to send his patients directly to the ophthalmic surgeon and not, as at present arranged under the scheme, to a dispensing optician at the clinic.—In this he was heartily supported by Dr. Helen Lukis (Kingston-on-Thames). In her area, she said, the scheme had been a failure. The dispensing optician attended at the clinic for two hours twice a week. It was impossible for an insured patient to be sure of being able to attend at those times, and dangerous delay might further be introduced, in an acute case, by the difficulty of making a telephone appointment with the ophthalmic specialist.—Mr. Bishop Harman, in replying, expressed his sympathy with the Cardiff motion, but said that at present employment of a dispensing optician in the scheme was necessary; his duty was to save the ophthalmic surgeon all office work, and he was there solely as a clerk; he had no right to direct either the patient or the doctor in their choice of ophthalmologist.

On the suggestion of Dr. Brackenbury, the meeting passed to the next business, since it was felt that though a more direct service between the doctor and the ophthalmic surgeon was desirable it could not be achieved in the present early stages of the scheme.

Development of Public Health Services.

Dr. E. K. Le Fleming (Bournemouth) referred to the position of the public health services throughout the country under the Local Government Act of 1929. In many areas the local authorities had been unwilling to do more than take over the poor-law duties and administer them without alteration. He proposed that the Council might ascertain and report on three aspects of the progress shown by local authorities—namely, in arranging the unification of health services, the better coöperation between municipal and voluntary hospitals, and the position of the medical officer of health in relation to the local authority and its health services.—Dr. Brackenbury thought it would be useful to describe the present deadlock to the meeting from another angle. It was almost wholly owing to the representation of the Association that it had been recognised that the medical officer of health of an authority should also be the me[illegible] officer to the public assistance committee. It [illegible] been indicated by the Ministry of Health [illegible] what lines it was desirable for the local author[illegible] to extend their activities, but the Ministry would n[illegible] have to wait until schemes were submitted for sanction by these authorities before taking further steps. Until such schemes were submitted it was impossible to criticise existing arrangements. In addition the Ministry had appointed inspectors in some areas to report on the health services, and action, of course, could be taken based on those reports. But relatively few authorities had so far submitted schemes to the Ministry and consequently information on progress in the country as a whole was meagre.—Dr. R. M. F. Picken (Cardiff) said that most of the authorities who intended to submit schemes had done so already, and that many of them did not provide for satisfactory unification of health services. The longer the Association waited without taking action the more difficult it would become to get the position changed. It was true that the joint efforts of the Association and the Society of Medical Officers of Health had done something to standardise the relation of the medical officer of health to the public assistance committees. But his status was only that of medical adviser to the committee, and not medical officer. Consequently, administration of health services was not necessarily in the hands of the medical officer of health. The meeting supported Dr. Le Fleming.

Payment of Hospital Staffs.

A resolution was moved by Sir Richard Luce, on behalf of the Council, that where a voluntary hospital gave in-patient treatment to patients for whom the local authority accepted financial responsibility, the members of the visiting staff of the voluntary hospital should be remunerated. He suggested that the local authority should pay to the hospital the maintenance cost of each patient plus an addition of one-quarter for medical services, and that of the total sum received 20 per cent. should be allocated to the visiting medical staff.

Considerable discussion followed. Dr. H. H. MacWilliam doubted whether the Committee would be able to arrange for such a proposal to be carried out, and Sir Ewen MacLean thought that opposition would be more likely to come from the governing bodies of the voluntary hospitals than the local authorities. It would be useful to find out, he considered, what schemes of this kind were already in operation.—Dr. Peter Macdonald thought it was a pity to hesitate over a new policy by stopping to inquire what was in practice in other areas. This was a matter for the education of hospital authorities and there was no reason why it should not become acceptable throughout the country.—Dr. T. W. Wadsworth feared that to ask for 20 per cent. was to ask for too much, but Sir Robert Bolam thought this was a very reasonable sum. The working-man governor of a hospital would be willing to recognise that the labourer was worthy of his hire and, though he might bargain shrewdly, would be willing to pay something. The demand was a reasonable one and should be pressed for.—Dr. J. Livingstone Barrow-in-Furness) had had a different experience. He had found that hospital governors were ready to admit that the labourer was worthy of his hire, but that they had no intention of giving it.—Dr. T. D. Ewart described an anomalous case in which the Hospital Saturday Fund had to pay 10*s.* for admission of a patient to the voluntary hospital and 1 for his admission to the municipal hospital. The medical profession wished the patient to have free ice of hospital, and he thought that if a position reached in which the voluntary asked more than municipal hospital, the local authorities might refuse to send their patients to the voluntary hospital. He warned the meeting against over-emphasis of the financial aspect.—Dr. F. A. Roper, Dr. Middleton Martin (Gloucester), and Dr. F. Radcliffe (Oldham) thought it undesirable to go back on the motion, as it would weaken the position of the staff in hospitals where the principle of payment had already been accepted.—Sir Richard Luce said that where voluntary hospitals were being used as a convenience by municipal authorities there was no question but that they should pay a reasonable sum for their patients, and the meeting approved that view.

The Problem of the Out-patient.

An active discussion followed the proposal in the Report of the Hospitals Committee on the Problem of the Out-patient, that the types of cases in out-patient departments fall properly into three groups—viz., casualty cases, consultation cases, including those retained for special treatment, and discharged in-patients.

Sir Richard Luce, who moved the acceptance of the report, said that at present out-patient departments were wasteful, and growing in rapid excess of the growth of population. Discharged in-patients and chronic cases should be referred back to the doctor. It should be realised that an out-patient department was a place primarily intended to give emergency treatment and to provide consultation and specialist opinion, and it should not be used as a dispensary for chronic patients.

Sir Ernest Graham-Little doubted whether it was the proper time to bring this motion forward, since it could not possibly be realised, and he moved that the report should not be approved. He asked whether the Council had considered carefully the composition of out-patient departments before saying that certain patients should not attend. The National Health Insurance Act had made no more than a temporary difference to the attendance at out-patient departments and the inference was that a certain number of insured persons went to hospital. In Guy's Hospital report for last year it was stated that 40 per cent. of out-patients came as consultation cases; of the remainder a considerable proportion were the non-insurable dependents of insured persons, and a certain section consisted of the new poor of the middle classes. It must be remembered that in many cases three-quarters of the hospital expenses were defrayed by associations corresponding to the Hospital Saving Association. If the public gained the idea that an arrangement had been made by private practitioners by which the patient could be prevented from going to hospital without his doctor's permission there would be considerable objection. The hospitals belonged to the public and the private practitioner should not be allowed to choose what cases should attend them.

Mr. H. S. Soutar thought Sir Ernest Graham-Little had somehow acquired a false idea of the object of the report, and he was glad that the Association now had the opportunity of rectifying it. The out-patient department should be the main point of contact between the general practitioner and the hospital, and the whole object of the report was to encourage patients to go to hospital and to make the conditions of their reception more favourable. It made all the difference to a patient attending hospital if he could produce a doctor's letter recommending him for treatment. The body of general practitioners in this country wished the hospital out-patient departments to be the consultative service of the State. The intention was not to protect the general practitioner but to make the out-patient departments more effective and to give the best service to the patient.—He was supported by Mr. McAdam Eccles, who thought that the present overcrowding was easily preventible; the chronic ordinary type of case should be seen once, diagnosed, and sent back to the proper official for treatment. The veteran of 60 or 70 attendances should no longer appear at the out-patient department.

Dr. H. D. Woodroffe felt that patients as a whole were not out for something for nothing; where they could spare a fee for a consultant they were ready to pay it, and maintained their self-respect by making the effort. Out-patient departments should provide a consultative service for those who could not afford to pay for it.—Sir Robert Bolam also emphasised the folly of wasting the service of out-patient departments by allowing them to be overburdened with chronic cases. The day had gone when the length of the list of out-patients treated was regarded as an index of the value of a hospital.

Sir Ernest Graham-Little's proposal that the report should not be adopted was lost by a large majority.

(To be continued.)

Enlargement of Arbroath Infirmary.—Sir John Cargill has now formally opened new wings which have been added to this hospital. The extensions, which have cost £17,680, include a children's ward and the enlargement of the nurses' quarters. The children's wing contains ten beds and two private wards. An old block has been converted into private wards, rooms for the resident medical staff, and a lecture hall.

MEDICINE AND THE LAW.

Industrial Disease Compensation: a Delayed Claim.

IN a Workmen's Compensation Act appeal, lately dealt with by the House of Lords, Lord Blanesburgh remarked of a certifying surgeon that "so far as professional skill was concerned he adequately filled his post, but as the filler up of a form he had shown himself a blunderer." The comment was not intended harshly. Learned judges are aware that accuracy and success in the filling up of forms are not automatic; they themselves have occasionally revealed inability to complete a printed will form so as to make a valid testamentary disposition of their property. The case before the House of Lords, however, displayed an unusual sequence of errors. First of all, the certifying surgeon, having to certify an industrial disease case, filled up the certificate with the wrong disease—or rather he described the disease as "epithelioma of the scrotum" instead of using the exact description from the statutory list of industrial diseases. Secondly, when faced with the words in the form, "I hereby certify that the disablement commenced on the —— day," he neither filled in the blank nor crossed out the sentence (as the form required him to do if the blank were not filled). This omission left it uncertain whether he meant to specify a date or to let the date of the certificate stand (under Section 43 (2) of the 1925 Act) as the date of disablement. The Act treats the date of disablement from an industrial disease as if it were the happening of an accident for which the workman can recover compensation. Section 14 of the Act stipulates that the employer must have notice of the workman's claim within six months. Here the certificate (the basis of the claim for compensation for the industrial disease) was dated July 24th, 1929; but that date was more than 12 months later than the date on which the workman left the employers' service. He had been an operative cotton spinner; the employers had closed down their works entirely on June 13th, 1928, and the man had not been employed since then. The firm repudiated liability on the ground that the claim was out of date. Three months later the trade union agent, acting for the workman, applied for a fresh certificate. The certifying surgeon thereupon examined the man again and sent another certificate, but made yet another mistake in filling up the form. He correctly described the industrial disease, but the date of disablement was specified as "the 22nd day of 1929," no month being inserted. After further correspondence, the certificate came back complete at last; it was dated Jan. 18th, 1930, and it specified the date of disablement as "the 22nd day of May, 1929." The claim, having thus been made as on Jan. 18th, 1930, was out of time; but the Act contains a proviso (to Section 14) safeguarding cases where the failure to make a claim within the time-limit is found due to "mistake, absence from the United Kingdom, or other reasonable cause." Did the facts of the case amount to "reasonable cause" for the delay? The House of Lords has answered "Yes." So the workman, suffering from epitheliomatous cancer after 17 years as a cotton spinner, fortunately does not lose his statutory compensation by reason of the errors which contributed to the delay in making the claim. But it is to be understood that Parliament intended the time limit to be some protection to the employers against improper claims; and Lord Blanesburgh adds the warning that the recent decision is not to be taken to countenance the workman "sitting on in the knowledge that he has contracted a disease and doing nothing to make good his claim."

B.M.A. Action against Drug Stores.

In the Chancery Division, on July 15th, the British Medical Association obtained an injunction against a defendant, trading in South-East London, who offered for sale drugs and medical remedies bearing the letters "B.M.A.," and who called his business the "B.M.A. Drug Stores." The defendant argued that "B.M.A." did not necessarily or exclusively denote the British Medical Association, and that he was entitled to use the letters. Mr. Justice Maugham, however, was satisfied that the acts of the defendant tended to injure the Association as being likely to cause its existing members to leave it and its prospective members to abstain from joining it. The Association was a purely voluntary body, dependent o subscriptions. People who saw the words "B.M.A. Drug Stores," or the defendant's shop-windo might think—and ordinary members of the publ would think—that the British Medical Associati was somehow connected with the shops. The ca resembled the proceedings on July 13th before M Justice Farwell, wherein the British Legion co plained that a company called the British Leg Club (Street), Ltd., was conducting a club at Stre in Somerset, which owed no allegiance to the Brit Legion; the members of the club were to be e Service men or other persons over age; there was requirement that the members should be members the British Legion. The defendant company answe that it had been incorporated in 1921, whereas t British Legion was not incorporated as such by Ro Charter until 1925. The judge said the name "British Legion" was well known in 1922, and it w a fallacy to say that a voluntary association cou not assert its right to the name; there was clear possibility of confusion even if there was no act evidence. Both the British Legion and the Brit Medical Association succeeded in obtaining the injunction desired.

A HOSPITAL TRIBUTE.—Sir Henry Dickens Common Sergeant of the City of London, recently unveiled in the male ward of the Passmore Edwards Hospital, a bronze tablet in recognition of the work of the Dickens Players, of Bowes Park, who have substantially helped the hospital by their performances.

COMPULSORY VACCINATION.—Mr. Arthur Greenwood, the Minister of Health, on July 15th received a deputation of Members of Parliament who urged that compulsory vaccination should be abolished, and expressed a hope that the Government would introduce or give facilities for the necessary legislation. They believed that all they wanted could be achieved by a one-clause Bill. The Minister said that he was bound to administer the law as it stood. The effect of the Local Government Act had been to place the administration of the Vaccination Acts in the hands of the larger local authorities, and he did not contemplate any drastic amendment of the law until those authorities had had time to gain experience of the operation of the Acts in force and furnish him with their views and advice. He believed that complicated and highly controversial legislation would be necessary to secure what the deputation desired. He must, in present circumstances, prefer the claims of other legislation to those of a Vaccination Bill. While, therefore, he could have no objection to the introduction of a Private Member's Bill as a means of testing public opinion, he could give no assurances either of support for such a Bill or of the introduction at an early date of Government legislation.

REVIEWS AND NOTICES OF BOOKS

The Histopathology of Skin Diseases.

By LEO MCCARTHY, M.D., Associate Clinical Professor of Dermatology, Georgetown University Medical School, &c. London: Henry Kimpton. 1931. Pp. 513. With 250 illustrations, 54 in colour. £5 5s.

THIS magnificent volume represents the first serious attempt to produce an original text-book of cutaneous histology in the English language. It has been crowned with success, for the illustrations are superb, and the author has succeeded in compressing the rather diffuse descriptive material into its important essentials. The result is, however, much more than a catalogue. By incorporating a brief clinical description of each morbid condition, he has succeeded in enlisting the reader's interest in the detailed histology, and has given vitality to a subject which has always suffered from the reproach of dullness. The work contains chapters on the normal anatomy of the skin and its appendages, pigmentation, atrophies, hypertrophies, acute and chronic inflammations, tumours, the dermatomycoses, and blood diseases. A complete chapter—as is only fitting, for much of the original work was done in America—is devoted to the precancerous dermatoses. In his description of diseases in which the ætiology is obscure or controversial, Dr. McCarthy maintains a neutral attitude. This policy is well illustrated by the section on lupus erythematosus. The present position is ably summarised in a few lines: "Although no definite proofs have been advanced to prove the tuberculous origin of the disease, most investigators are agreed that it is in some way intimately connected with tuberculosis. At the present time nothing more definite can be said." Again, "it should be mentioned that the histological picture of L.E. does not reveal even the slightest similarity to that of tuberculosis of the skin. . . ." He is careful to avoid the temptation to enter into a dissertation on a question which has troubled the world of dermatology for a decade.

The difficulties of nomenclature in the group of parapsoriasis are dispelled by a neatly tabulated list of equivalents according to the French and German schools; the various synonyms which have greatly added to the confusion surrounding this group are also tabulated and will be found of much value. Mycosis fungoides is classified with the skin manifestations in diseases of the blood, such as myeloid and lymphatic leukæmia. Some beautiful microscopical illustrations amplify the description of this fatal disease, and make it easy to realise and remember the salient features of the three accepted stages. In the same chapter it is suggested that in many cases originally described under the name pityriasis rubra of Hebra the diagnosis was not confirmed by blood counts; such cases may indicate only a sign or symptom such as universal erythrodermia, and not a disease sui generis. Earlier writers may have included such various entities as mycosis fungoides, lymphatic erythrodermia, or tuberculosis in the same group. This work is likely to remain a standard text-book of the histopathology of the skin in the English language until the science of histology itself gives place to new methods of cutaneous investigation. Its appearance is an event in dermatological literature for which the specialist will be grateful.

Backache.

By JAMES MENNELL, M.D., Medical Officer, Physicotherapeutic Department, St. Thomas's Hospital. London: J. and A. Churchill. 1931. Pp. 190. 10s. 6d.

FEW symptoms are more baffling than backache, or, in spite of its common occurrence, more inadequately dealt with in ordinary surgical text-books. Dr. Mennell has written a very useful little book on the subject. He says in the preface that he was prompted to undertake this task because "of the injustice of the judgment formed, in the early period of my study of backache, that all patients grossly exaggerated their symptoms and that the symptoms themselves were, to a great extent, neurasthenic." The tendency to regard these sufferings lightly is still too prevalent, and it is this attitude that leads a patient to seek relief at the hands of unqualified practitioners, often without the knowledge and against the advice of his own doctor. When one reflects that the text-books used by those who qualified some 10–20 years ago devoted more attention to "railway spine" than to the strains of the sacro-iliac joints, little blame can be attached to the doctor for his failure to appreciate how much can be done to-day, by orthopædic methods, to relieve backache. Dr. Mennell has not attempted to compile a big thesis, embodying the views of other authors, but contents himself with a clear, simple, and short account, illustrated by admirable diagrams, of the results of his own wide experience. Throughout he keeps in view the needs of the general practitioner, and the book is so arranged that, except for one important omission noted below, information on any particular point can be found without reading through the whole book. This monograph should find a place in the libraries of all practitioners, for it is only by acquainting them, and through them the general public, with the aims and methods of the orthopædic surgeons and physicians that the glamour and mystery surrounding the practices of the unqualified bone-setter can be removed. The omission of a substantial section on backache associated with childbirth mars the book. Dr. Mennell mentions this aspect of the subject only patchily and rather by implication. The symptom is so tiresome and so common, both before and after labour, that the practitioner might reasonably expect to find a fuller discussion of it in a work of this kind. Not even under the headings of childbirth, labour, post-partum, pregnancy, or sacro-iliac joint is there any reference made to it in the index. This is the only serious fault we have to find, and one which can easily be made good in future editions.

Hay-Fever, Hay-Asthma.

Its Causes, Diagnosis, and Treatment. Third edition. By WILLIAM LLOYD, F.R.C.S., late Surgeon in Charge of the Nose, Ear, and Throat Department, Kensington General Hospital. London: Straker Brothers, Ltd. 1931. Pp. 124.

THE last edition of this book was published 23 years ago. The first chapter consists of a review of opinions on the exciting causes of hay-fever, but the more recent work on protein sensitisation is not discussed. The second chapter is on the predisposing causes, the third on the symptoms, and the fourth on the treatment of hay-fever. The treatment advised by Mr. Lloyd consists chiefly in the removal, if present, of intranasal abnormalities, the cauterisation of hypersensitive areas, and the application of astringent lotions. The author does not appear to believe in individual idiosyncrasy to animal exhalations, which is generally regarded as an important factor in many cases of asthma.

A Text-book of Surgery.

By JOHN HOMANS, M.D. London: Baillière, Tindall and Cox. 1931. Pp. 1195. 40*s*.

THIS book is really a series of lectures for undergraduate students. It is perhaps a little uneven, and its recommendations are not quite explicit enough. It is well to instil principles, but the student will want to know more, for example, that the mere fact that iodine should be administered before operation for exophthalmic goitre. He will want to know how to give the drug, and in what dosage. Dr. Homans writes with an easy style, and an attractive feature of his book is the return to line drawings for purposes of illustration. The pictures are well executed and much more expressive than many of the photographs it is now customary to provide in modern text-books. At the end of the book the names of all the authors who have been mentioned in the text are placed in alphabetical order with references to their original work.

Trial of Alfred Arthur Rouse.

Notable British Trials. Edited by HELENA NORMANTON, Barrister-at-Law. Edinburgh and London: Wm. Hodge and Co. 1931. Pp. 316. 10*s*. 6*d*.

THE trial of Rouse for the so-called "blazing car murder" had no conspicuous medico-legal interest. The Crown claimed to establish that the fire was not accidental and that the charred body could not have got into the position in which the victim died unless placed there while he was unconscious. On the former point the evidence of mechanical engineers was important; on the latter that of Sir Bernard Spilsbury. The presence of a single human hair on the mallet found 14 yards from the burnt car was not stressed. Rouse's own behaviour and statements (both before and during the trial) contributed largely to his conviction. Mrs. Helena Normanton, who edits the case in the Notable British Trials series, tells the story in a comprehensive introduction with dramatic gestures and moral reflections perhaps not inappropriate. In an Appendix she gives significant extracts from Rouse's medical records; he was wounded in the head at Givenchy. She also prints, and shows faith in, Rouse's confession as published in a newspaper on the day after his execution. One statement therein confirms a rumour current in the Temple at the time. "In my attaché case," he wrote, "was my identity disc, which the police have; I intended to put it on the man in the car so that people would think it was me; I forgot to do so." His wife's statement to the police, not yet released by the Home Office for publication, might be a crucial document. Rouse visited her before 7 A.M., a few hours after the car was burnt; later in the day the police took her to attempt identification of the remains. She was not called as a witness by her husband, nor did the judge comment on the omission.

One striking feature of the case was the total failure to identify the dead man; at first the body was thought to be that of a woman. In the preliminary proceedings before the magistrates, several women were called to speak of their relations with Rouse, and a police officer quoted his statement "my harem takes me to several places." Early and widely published, this evidence (subsequently excluded at the trial as irrelevant) alienated popular sympathy from the accused. His counsel could fairly complain that it prejudiced his chance of a fair trial. It seems odd, indeed, that magistrates, when investigating what is obviously a grave charge beyond their summary powers, cannot limit the inquiry to the minimum necessary for deciding whether or no there is a prima-facie case for committing the accused for trial. Perhaps by the fault of the prosecution or by that of the defence, magisterial proceedings are often far too long. It is, however, as Mr. Justice Avory observed on the appeal, difficult to say, when an accused person makes a statement derogatory to himself, whether it may not have some object connected with the defence. The Court of Criminal Appeal found no cause to disturb the result of the trial. Much comment on the case was published in the newspapers between trial and appeal. Is such publication contempt of court when there is no longer a jury to be influenced thereby? Lord Hewart's warning suggested that the answer might be in the affirmative.

The Physical and Radiological Examination of the Lungs.

Second edition. By JAMES CROCKET, M.D., D.P.H., F.R.C.P.E., Lecturer on Tuberculosis, Glasgow University; Visiting Physician, formerly Medical Superintendent, Consumption Sanatorium of Scotland, Bridge of Weir, &c. London: H. Lewis and Co., Ltd. 1931. Pp. 296. With illustrations, including 40 plates. 16*s*.

THIS book has been largely rewritten since t first edition appeared nine years ago, even the tit having been changed. For the student it is an excellent text-book, since stress is laid on the importance of giving due weight to the smallest detail of physical examination. A chapter deals with the measurements of the chest, vital capacity, and various tests of respiratory force; tables are given showing the average weight, measurement, and vital capacity of the normal individual. A very full chapter describes the X ray examination of the lungs. It is satisfactory to observe that adequate space has been devoted to the X ray appearances of the healthy lung, and the student is told what shadows may be regarded as normal. Bronchoscopic examination and the examination of the larynx is also described. At the end of the book is a glossary of terms used in connexion with the examination of the lungs. Some of these are helpful, but it is a pity that so many different signs, each bearing the name of its inventor, should be given. It is puzzling for the student to try to remember proper names, and he should not be worried with those which have no real value.

Several classifications of pulmonary tuberculosis are set out; the one used by the author is a modification of the Turban-Gerhardt classification, which shows not only the degree of systemic involvement, but also the presence of complications, such as laryngitis, and whether or not a large number of tubercle bacilli are present. The book is well-produced and illustrated.

In three mines chosen as …g representative of the whole group under his …arge inoculation was discontinued, while it was …ntinued in the other mines of the group. The …verage native population in the uninoculated mines was 30,000, and in the inoculated ones 50,000. On comparing the figures for 1928 and 1930 it was found that in the inoculated group the attack-rate for 1930 was higher than for 1928, though the death-rate was lower, whereas in the uninoculated mines there was both a lower attack-rate and a lower death-rate. Mathematical examination of the actual figures indicates that inoculation is actually unfavourable to the reduction of the attack-rate from pneumonia. The advocates of inoculation have stated that the type of pneumonia on the Rand has changed, as observed clinically, from that prevailing in 1920. It is, perhaps, difficult to measure most clinical manifestations, but one, the fall of the temperature, can be accurately recorded, and it has been stated that in the modern cases the temperature tends to fall by lysis. Dr. ORENSTEIN claims that this is incorrect, and publishes tables showing that in 975 consecutive cases in 1912 crisis occurred in 34·7 per cent.; in 269 consecutive cases in 1929–30 the temperature fell by crisis in 75·4 per cent. From these and other data it is concluded that there has been no significant change in the clinical manifestations and time of attack of pneumonia during the period under review. Furthermore, post-mortem evidence lends no support to the view that there has been a radical change in the type of the disease. Finally, Dr. ORENSTEIN discusses the view that the inefficacy of the vaccine in current use is due to an alteration in the bacterial flora of pneumonia, and points out, even when the vaccine corresponded to the dominant flora found in pneumonia locally, no protection at all comparable in degree with that which follows antityphoid inoculation was ever demonstrated; and he also suggests that, on general grounds, protection is hardly to be expected against a disease an attack of which confers little or no immunity.

It is, of course, notoriously difficult to conduct crucial experiments where human beings are concerned, but it is not a little disquieting to find that the elaborate investigations which were

…ylaxis in Pneumonia, Journal of the Medical …th Africa (B.M.A.), June 13th, 1931, p. 339.

carried out on the Rand are open to such stringent criticism. If experiments conducted with the assistance of a medical organisation as efficient as that on the Rand, and with many thousands of subjects, can be as inconclusive as these apparently were, what success can be expected from the application of the experimental method to other aspects of clinical medicine? For in few problems will the conditions be less complex or the point at issue more clearly defined. Dr. ORENSTEIN no doubt would claim that these experiments did, in fact, achieve a negative success, but it is doubtful if the exponents of prophylactic inoculation will agree with him; their reply will no doubt be forthcoming in due course, but, in the meantime, Dr. ORENSTEIN would seem to have established his thesis.

◆

THE MEDICAL OFFICER OF HEALTH: PAST, PRESENT, AND FUTURE.

QUIETLY, without disturbance of public administration, but also without any striking reform of procedure, the transfer of poor-law functions which was one of the main purposes of the Local Government Act, 1929, has taken place. Medical officers of health in counties and county boroughs are the responsible "advisers" of the public assistance committees, although their influence upon the deliberations of these committees inevitably varies in different areas. It may be presumed that local committees representative of the voluntary hospitals, in terms of Section 13 of the Act, have been set up, although outside of London and a few of the bigger provincial towns there is not much evidence that they have got down to business seriously. County councils are proceeding with the duty, imposed upon them by Section 46 of the Act, of rearranging the sanitary districts within their boundaries; and closely linked up with this problem is the very important obligation placed on them by Section 58 to ensure that every such district shall, when the opportunity of change arises, be served by a medical officer of health who is not engaged in private practice. It is fitting that this year, for the first time, the president of the British Medical Association is a full-time medical officer of health. Dr. WILLOUGHBY reveals in his presidential address, which we publish in abridged form on p. 171, a sympathetic perception of the reasons for the difference in outlook which sometimes impairs cordial relations between public health officers and practitioners. This difference should diminish now that medical officers of health have responsibilities in connexion with municipal hospitals, which must be largely curative, and, on the other hand, efforts are being made to enlist the coöperation of practitioners in the preventive work of clinics.

If the counties and county boroughs approach their tasks with a real appreciation of the objects underlying the Local Government Act, if local pride and the entrenchment of the old spirit of bumbledom in the new public assistance committees can be counteracted, we ought to be able to look forward to a new era of unification in the public medical services and of friendly coöperation between these and the various voluntary organisations whose fields of activity are being, if gradually, invaded. It is, perhaps, appropriate that the parting of the ways should be marked by the publication of historical accounts of the growth of public health organisation in places which have been in the van of sanitary progress since CHADWICK, CHESTERFIELD, SIMON, FARR, and other men of vision awakened the public conscience to the meaning of the hygienic disasters of a hundred years ago. In his book, "Health at the Gateway," Prof. E. W. HOPE[1] describes in popular language the development of the health department of Liverpool of which he was the head for many years. He deals chiefly with the special problems arising from the staple industry of that city—which is shipping—its peculiar exposure to the risks of infection from European transmigrants and the overcrowding and disease which arose from mass invasions from Ireland during the "hungry forties." The gradual evolution from a department consisting of a part-time medical officer of health working single-handed to the present large and complex organism is traced throughout the intervening years. The problems of Glasgow were not unlike those of Liverpool and an even more informative account of them and the way in which these were met was provided last year by Dr. A. K. CHALMERS,[2] who was formerly medical officer of health of that city. Dr. CHALMERS provides a fitting sequel to the classical writings of J. B. RUSSELL[3] which he brought together and edited in 1905. In these books the foundations [illegible] service are recounted and there is traced the slow synthesis of a health department by the attraction to it of one element after another, so that *it has* been gradually prepared for its latest and perhaps its greatest extension of functions, that which has come since these writers ceased to be active agents in the process. Looking back on the early days of preventive medicine in these cities we cannot fail to be impressed with the fact that their first medical officers of health were enthusiasts and missionaries. They were pressed to the service by a realisation that their day-to-day work as medical practitioners was nullified by conditions of living that must be rectified by large-scale operations. They were physicians by profession, propagandists by calling, and administrators by force of circumstances. Sir WILLIAM GAIRDNER was at one time professor of medicine and medical officer of health of Glasgow and perhaps it was this eminently desirable combination of appointments that gave to the health department of that city the scientific bent which has marked its subsequent activities. An even more striking instance of science wedded to administration may be found across the Atlantic in the life of the late HERMANN

[3] Public Health Administration in Glasgow.

BIGGS of Yale, recently commemorated[4] by his friend and colleague Dr. WINSLOW. Among the many appointments which BIGGS held were those of bacteriologist, consulting physician to various hospitals, professor of anatomy, professor of materia medica, professor of therapeutics and clinical medicine, and professor of practice of medicine. He became successively director of the Rockefeller Institute and Commissioner of Health for New York City, general medical officer of its reorganised health service from 1902 to 1913, and, finally, Commissioner of Health for New York State. What more appropriate career can be imagined for a medical officer of health, but how is it possible to introduce such men to the head of affairs in an established service such as ours?

The public health service in this country has grown out of all recognition since its inception. Without losing its environmental interests it has come to embrace almost the whole range of clinical work. The men who have grown up in it during the last 30 years or more have been actively engaged in the treatment of certain diseases, some of which are almost side issues of medicine. To an increasing extent institutional organisation for the treatment of all sorts of disease is bound to be a dominating interest for the medical officer of the future, now that the functions of the poor-law have been transferred. If this integration of the medical services is to reach its full fruition in benefit to the communal health, it is imperative that these officers should be well and specially trained. The General Medical Council has shown its realisation of this need by issuing new regulations for the diploma of public health which, incidentally, are causing the medical schools some concern. But it is even more important that the method of selection of men for the senior posts of the service should be inquired into. There is none of their responsibilities to which lay councils cling more jealously than that of making appointments, and yet it is impossible to believe that they are fit for this task without expert guidance. The universities have met similar difficulties by the formation of appointments boards and this suggests a way which the Ministry of Health might point out to the councils, at least of counties and county boroughs. We fear, however, that the acceptance of any such proposal by local authorities would be long delayed. The Mayo librarian case in Ireland, where appointments have been centralised, shows the need for caution, but the successes of the Irish scheme have also their lessons for us. The fetish of administrative capacity has to be exorcised. Clearly it is desirable that medical officers of health should be capable of applying medical knowledge to the day-to-day routine of their office, but it is hard to see how sound administration can be based on any foundation but professional attainment and a close contact with the results of medical research. The medical officer of health, as BIGGS insisted, should be relieved as far as possible of petty office routine. Much less office discipline of medical staffs, for instance, would be necessary if appointments were always made on merit. The medical officer of health should be first of all a man of professional and academic attainment and in the second place an administrator. There is a danger that the present method of making appointments is tending in the opposite direction.

NUTRITIONAL ANÆMIA IN INFANCY.

FOR the past five years Dr. HELEN MACKAY has been investigating simple anæmia in infants. Some of her earlier conclusions regarding the prevalence of this condition and the means of preventing and treating it have already been published and are familiar to those who are interested in pædiatrics. Her more recent findings, however, emphasise the immense practical importance of this pathological condition, and the full account of her work, which has just been published,[1] is likely to prove of great service to those concerned in any way with the welfare of the infant. Her main thesis is that simple anæmia in infancy resulting from iron deficiency is extremely common and is directly or indirectly responsible for a great deal of ill-health among infants, because it is associated with a lowered resistance to infection. The statement has often been made that this type of anæmia is rare. By examining blood samples from healthy breast-fed infants and from infants in whom the existence of anæmia was ruled out as far as possible by appropriate prophylactic measures, it has been possible to draw a curve representing the normal hæmoglobin concentration during the first 12 months of life. Shortly after birth this concentration falls from its high level of 120–140 per cent. and reaches an average of 99 per cent. in the third or fourth week; by the second or third month it has fallen to 69 per cent., but then rises until at five or six months it reaches 80 per cent., where it remains until the end of the first year. The frequency of anæmia in the East End of London has been measured by the examination of more than 1000 infants. Only 10 per cent. of artificially fed infants and 16 per cent. of breast-fed infants showed a hæmoglobin concentration of 80 per cent. or more after the age of 5 months. The fact that appropriate treatment caused 69 per cent. of the infants to reach this hæmoglobin level is taken as evidence that lower levels of hæmoglobin concentration do, in fact, represent a true state of anæmia, and this conclusion is almost certainly justifiable.

That the main cause of this anæmia is a deficiency of iron, and possibly also of other metals such as copper, is suggested from the results both of animal experiments and of prophylactic trials in clinical practice. The production of nutritional anæmia in young animals by feeding them after weaning exclusively on milk has been recently reported from several laboratories, and it has been shown that this type of anæmia can be cured by the addition of iron together with traces of copper. The iron content of cow's milk is known to be lower than that of human milk, and is not, in fact, sufficient to supply the infant's needs after he has exhausted the reserves normally stored in his liver at birth. Dr. MACKAY has shown that the regular addition to a milk diet of a soluble iron preparation is remarkably successful in raising an infant's hæmoglobin concentration to the "normal" level. Iron and ammonium citrate was the preparation used, and it was either given in a mixture or was incorporated with the dried milk given to the infants in such proportions that from 4½ to 9 grains a day were taken. This preparation was shown to contain traces of copper, so that part of its effect may have been due to this metal. Although this simple or nutritional anæmia has been shown to be extremely common, at least in the East End of London, and to be readily amenable to treatment, it often appears to be associated with little or no general disturbance of health and might therefore be considered of no great practical importance. But evidence is presented in this report which shows that this view is untenable. Among Dr. MACKAY's cases the morbidity-rate of infants receiving prophylactic doses of iron was only about half that of control cases not receiving iron. Certain types of infection are known to predispose to anæmia, and this anæmia itself appears to reduce resistance to infection; the vicious circle can be broken by the administration of iron, and, in fact, many infants with chronic infections were observed who had an associated anæmia and who improved dramatically as soon as iron treatment was instituted. Moreover, the infants receiving iron gained in weight at a greater rate than the controls.

[4] The Life of Hermann Biggs. By G. E. A. Winslow, D.P.H., Professor of Public Health, Yale School of Medicine. Philadelphia: Lea and Febiger. 1929. 15s.

[1] Nutritional Anæmia in Infancy, with Special Reference to Iron Deficiency. By Helen M. Mackay. Assisted by Lorel Goodfellow. With a Statistical Appendix by A. Bradford Hill. Medical Research Council Special Report Series, No. 157. London: H.M. Stationery Office. 1931. Pp. 125. 2s.

The evidence presented in this report, which has been subjected to statistical analysis by Mr. A. BRADFORD HILL, D.Sc., points conclusively to the existence and the importance of the condition of iron deficiency, or nutritional anæmia, among infants in this country. The simplicity of the treatment recommended for its prophylaxis or cure should ensure its wide adoption and the disappearance of a deficiency disease with its unfavourable effects on the health of the infant community.

ANNOTATIONS

NARCOTIC DRUGS: A NEW CONVENTION.

THE conference on the limitation of the manufacture of morphine, heroin, cocaine, and other narcotic drugs, to which reference was made in our issue of June 27th (p. 1407), was in session at Geneva from May 27th to July 13th. It has prepared another convention, which in some particulars is supplementary to the Opium Conventions of 1912 and 1925. As intimated in our annotation, the "quota scheme," whereby due proportions of the world's requirements of the drugs referred to were to be produced respectively by the eight countries which are at present engaged in their manufacture, did not commend itself to the conference. That scheme, espoused by the British delegate and backed by the advisory committee of the League, as well as by the London conference of manufacturing countries, found few supporters. The more complicated scheme, whereby annual estimates of the products of each manufacturing country are not to be exceeded, whether for export, conversion, government stocks, or home consumption, was adopted. Codeine, dionin, and peronin are to be brought within the convention, while heroin is only to be exported to governments. New preparations derived from opium or coca leaves are not to be manufactured unless the government of the country of origin is satisfied as to their medical or scientific value; nor shall such be exported until the opinion of the Health Committee of the League of Nations as to their capability of causing addiction has been declared. It is noteworthy that this new convention will not be applied unless and until 25 nations, including four of the eight manufacturing countries, shall have ratified it. The effectuation of an international treaty has to proceed by way of signature, ratification, putting the convention into force, legislation, and enforcement of legislation. The Geneva Convention of 1925 required ratification by ten Powers, including seven represented on the Central Board, of which two were to be permanent members of the Council of the League. It will be recalled that it was several years before that convention came into operation and that some of the more important opium- and coca-producing countries are still outside its scope. Statistics recently issued by the League of Nations show how much can be achieved by effective legislation based on the existing conventions, as in the case of the Dangerous Drugs Act, 1920–1925 of Great Britain. By such means it appears that the appalling illicit traffic in narcotic drugs can be successfully reduced, while their medical and legitimate uses are not unduly restricted.

THE CARE OF THE DEAF.

WE have on many occasions called attention to the neglect by the State of deaf persons who, if properly trained, could be made into useful and self-supporting citizens, and the matter has been constantly put before the public by the National Institute for the Deaf. Ministers of State, whose departments could do much to ameliorate the lot of these afflicted and handicapped persons, have expressed official sympathy under two administrations, while last year, at the annual meeting of the Institute, Mr. Baldwin gave an eloquent and thoughtful address on the subject. Apathy, however, has not been overcome, as was indicated by Lord Charnwood, the President at the annual meeting at Church House, Westminster, recently. He said that the average man and woman wholly failed to appreciate the character of the affliction, while, owing to lack of general knowledge, the necessary money for carrying out the beneficent work of relieving it was not forthcoming. Yet, he said, the sum needed was very small as compared with the response given to appeals for other charitable objects. The report of the executive committee of the Institute, which has reached us, emphasises Lord Charnwood's words. This shows that the debt on Richardson House, which now provides a home for a small group of deaf women, amounts to £1237, and that during the past year, apart from a legacy of £500, the ordinary current income has fallen slightly short of the expenditure. The legacy, which ought to have been used for endowment purposes, has been expended on current needs, and, as a matter of fact, a considerable part of the Institute's investments have had to be similarly treated. It is clear that there is as yet no general recognition of the fact that the burden of the deaf on the country might be turned into a valuable asset if the subjects of the disability received proper training.

MEDICAL EDUCATION IN RUSSIA.

The Russian government has to provide for a large primitive population spread over a vast area and is trying to create in a few years an effective medical service. The Chinese problem is in some ways similar, and it is interesting to hear comments on the Russian scheme from an experienced educationist in China. Dr. F. R. Dieuaide[1] chiefly criticises the establishment of medical schools cut off from association with universities. Such schools, he thinks, tend to run downhill, and their staffs must be constantly refreshed by drafting in men from intellectual centres. He fears for the new Russian system that a time will come when its graduates are equipped with out-of-date technique and can no longer satisfy the very needs that called them into existence. Technical schools of medicine will, he says, exist in any case, but it does not seem desirable to create them deliberately. Medicine is a living, growing field of human interest inextricably bound up with other sciences, and the physician needs not only the highest possible technique but all the intellectual power of which he is capable. In public health, for which Russian doctors are to be specially trained, this need is the greater by reason of the extended opportunities which this work offers. For this reason Dr. Dieuaide rejects the Russian solution of a large number of medical schools with low requirements and short courses.

ELECTRICAL APPARATUS AND ACCIDENTS.

During the last few months three serious casualties at hospitals have been reported in the press. In all of them the accident has been traced to some fault in the design, use, or condition of an electrical appliance. In one case an electric pencil light, used for examining the patient under an ether anæsthetic, caused a serious explosion, which was due to a spark resulting from a bad contact between the lamp and its holder. The second mishap was an explosion during an operation involving the use of diathermy apparatus. The third was attributed to faulty insulation in a radiant-heat apparatus, which resulted in a short circuit through the patient, and thence to the metal framework of the bed and the waterpipes. Two of these accidents were fatal and the other serious in its consequences. In two of them no harm would have been done but for the explosive nature of ether vapour when mixed with air, and they emphasise the warning that whenever ether is used the greatest care is necessary on the part of everyone concerned in the use of any appliance which is capable of raising the temperature of the air above the flash point. It is disturbing to think that there must be pencil lights, similar to that employed in one of the accidents cited, still in use. If the explosion was due to a bad contact between the lamp and the lampholder—and there is no reason to doubt the conclusion—this argues that the design leaves much to be desired. The avoidance of these accidents in future, then, is largely bound up with circumspection and with placing of faultless appliances in the hands of the practising medical public. Some few years ago, as part of a scientific instrument exhibition, an instructive section was devoted to those showing faulty design. It is a commonplace for anyone using electrical appliances to notice the rather casual way in which connexions are made between conducting wires and the plugs and switches to which they lead, and it is almost always at these points of contact that wires get frayed or break away from their bearings. It seems that ingenuity is still required to give flexibility in use and yet leave no weak spots.

Surgeons and other medical men have every year an addition to the electrical appliances put at their service, and there is an urgent need for guarantees of complete safety, such as we have had during the last few years in X ray work. In this department recommendations have been made which appear to give real safety where once there was real danger.

CARCINOGENESIS WITH DIBENZANTHRACENE.

The neat appropriation to cancer research of a method of preparing a complex chemical substance is described in the annual report of the British Empire Cancer Campaign, which is noticed on another page. If it were still necessary to emphasise the fact that pure research, conducted with no utilitarian bias, may find practical applications in the most unexpected quarters, this train of events would provide a cogent example. In February, 1929, a method for the synthesis of 1 : 2 : 5 : 6 dibenzanthracene was published in a German chemical journal having no connexion with cancer research. This is only one of a great number of new compounds constantly being produced by organic chemists, and there would have been nothing to draw attention to its possibilities as a carcinogenetic agent had not Mr. J. Hieger, working at the Cancer Hospital under the general direction of Prof. E. L. Kennaway, been on the look-out for new compounds closely related to benzanthracene. For he had previously noticed the resemblance between the fluorescence spectrum of benzanthracene and that of a cancer-producing coal tar, and the association had led him to seek a pure chemical substance which would replace coal tar as a carcinogenetic agent. Benzanthracene itself, which consists of four benzene rings fused together, has only feeble cancer-producing power; in a series of 70 mice painted with it, only one papilloma appeared. But the addition of one more benzene ring in a certain position (dibenzanthracene) has given 58 cancers and 9 papillomas in 190 mice, of which 104 lived for more than six months. Experiments are being undertaken with closely allied compounds, which vary greatly in carcinogenetic activity. The two compounds which, up to the present, have been found most active differ from the almost inactive parent substance, benzanthracene, in that the molecule, as shown in the conventional graphic formula, is extended at the lower left-hand corner, in one case by the *iso*propyl group $\begin{matrix}CH_3\\CH_3\end{matrix}\!\!>\!CH-$ in the other by a fifth benzene ring. The question whether this type of molecular structure has any general significance in cancer production must be decided by much further work. Many other compounds besides those mentioned above are being examined.

Dr. Cook has devised a method for preparing dibenzanthracene in a very pure state, and seems to have disposed of the possibility that the action of this compound is due to some unknown impurity. The usual method of producing tumours is to paint the skin with a saturated benzene solution of the compound in the strength of about 1 in 400; but a solution as dilute as 1 in 4000 has produced carcinomata after one year's painting. It is suggested, with good reason, that painting with crude tar should henceforward be considered obsolete for any purpose where the actual process of carcinogenesis is under study. All such experiments should now be carried out with pure substances. When one paints tar on the skin to produce cancer he is applying many scores, or even hundreds, of compounds, of which perhaps only one or two are actually required. All the superfluous substances may have their own confusing effects, and some of them, such as the phenols, are very irritating. Tar painting is suitable where the chief object in view is merely to obtain a number of tumours, but when the mechanism of their production is being studied the use of pure substances is obviously preferable. The examination of other chemical substances allied to benzanthracene continues, and it is anticipated that substances with far more powerful carcinogenetic properties will be discovered.

---

THE LABORATORY DIAGNOSIS OF MALARIA.

ELEMENTARY as they may seem, the laboratory methods which make malaria parasites readily visible give constant trouble to the isolated medical man in the tropics. This point has been impressed on Colonel R. Knowles, of the Calcutta School of Tropical Medicine, by the almost daily receipt of letters from all parts of India asking for help in difficulties of this kind. He has made this help generally available in a paper[1] in which he explains in precise and valuable detail how to prepare and examine thick and thin blood films and make Bass's cultures of suspected blood. For each procedure there is explained exactly what to do, what not to do, and how best to retrieve mistakes if, haply, correction is possible; and occasion is taken to point out how dependent is diagnostic success on payment of the most painstaking attention to detail, a warning which is equally needed in some other branches of tropical medicine. For all these matters the paper itself will be extensively consulted, and in this way the author's valuable experience will reach a wide circle.

But it is appropriate to state here certain difficulties which the personal factor introduces into the recognition of malaria parasites. At the end of a six months' course the 45 members of a class studying for the Calcutta Diploma in Tropical Medicine were given two tests of their skill in recognising the different species of malaria parasites. In the first the microscopical field contained a single parasite, and only 41 per cent. correctly named it; in the second, in which the slide might be moved and examined at leisure, 80 per cent. gave accurate answers. It is concluded that the latter figure displays the accuracy of a brigade or divisional laboratory. These same tests were then voluntarily submitted to by nine experts. In the first test there was agreement to the extent of 63 per cent.; in the second to 93 per cent. These tests, it is pointed out, show that the custom prevalent in certain laboratories of announcing the species of malaria parasite concerned, when only one or two specimens have been seen, will be wrong as often as not, and they make it clear that in this matter there should be some accepted standard of time spent in examining a specimen. It is suggested that this should be ten minutes, of which eight should be spent over a thin film and two over a thick one. It is felt that this is as much time as most laboratory workers can be induced or can afford to spend on a single case. In every instance it is held that a Bass's culture should also be made. Were the adoption of such a standard generally contemplated the demand would certainly arise for information as to the percentage of accuracy, in both the fact and kind of infection, which it actually attains in cases in which plasmodia are only scantily present in cutaneous blood.

STAPHYLOCOCCAL INFECTION OF THE NOSE AND LIP.

THE region of the nose and upper lip, drained by the anterior facial vein, has aptly been called the "danger area," with regard to staphylococcal infection. During the last two years attention has been directed, by a number of articles reporting fatal complications, to the serious consequences which may follow such infections. There is obviously some peculiarity about staphylococcal infections, apart from their close connexion with the cavernous sinus and the meninges, which render them dangerous and often fatal when occurring at this site. A carbuncle of the neck is a common affection, but when it occurs in a young and healthy adult the results are very rarely fatal. The thick skin and the presence of a dense subcutaneous tissue help in the production of a natural barrier to the infection, and when the subcutaneous veins are involved they thrombose and collapse, and thus assist in shutting off the infection. Dr. Irwin I. Koslin points out[1] clearly that the response to infection in the so-called danger area is different. The thin skin and subcutaneous tissue allow early and easy invasion of the veins, which are themselves different in structure; they are valveless and are "patent veins," which do not collapse when thrombosis occurs. They have, moreover, a very free connexion with the cavernous sinus through the ophthalmic and angular veins. There is no definite evidence as to the means by which infection spreads from the primary focus to the cerebral sinus, though it must do so in one of three ways—by the lymphatics, by direct spread of thrombosis, or by a retrograde embolus.

The point of practical interest is how to deal with a small primary focus on the nose so that the dreaded spread to the cavernous sinus may be prevented. At the beginning of the century treatment on ordinary surgical lines was advocated, and incision and drainage was generally accepted, just as excision of a carbuncle of the neck is widely practised now. The results of such excision are excellent, but the results of surgical intervention when the focus is on the nose were extremely bad. It is generally accepted that incision, squeezing, ligature of the angular vein, and other active measures are dangerous in that they may break down the delicate barrier being erected between the body and an invader that will rapidly kill once the defences are broken through. It seems desirable, however, that conservative methods, such as hot bathing, fomentations, saturated magnesium sulphate dressings, poultices, and even ultra-violet light treatments should be supplemented at the right moment by puncture and cauterisation. In an article on cavernous sinus thrombosis as a fatal complication of minor facial sepsis[2] Mr. Scott Brown suggests that at the first definite sign of pointing, it is safe and wise to puncture a small focus with a sharpened orange stick which has been dipped in carbolic; larger or "blind boils" he treats with liquor hydrargyri nitratis acidus applied to the core, precautions being taken to avoid overflow of the acid on to the skin. It is important to emphasise the serious results that may follow these minor infections, but those who are fighting them and vividly anticipating the development of an orbital cellulitis, chemosis, or proptosis, should remember that, though septic foci on the nose, lip, and particularly the naso-labial fold, are common, Dr. Koslin collected only six fatal cases from the records of the Lebanon Hospital between 1922 and 1930, and Mr. Scott Brown only the same number from St. Bartholomew's Hospital over a similar period.

EVOLUTIONARY TENDENCIES IN TEETH AND JAWS.

IN man the growth of a larger brain, and the cultivation of its complicated functions, call for much more time than is required for the development of other creatures, and during the years thus occupied the eruption of the teeth is delayed. In his lecture to the International Orthodontic Congress in London on Monday Prof. Elliot Smith pointed out that most of the problems responsible for the creation of the orthodontic profession arise out of the circumstances created by these delays in the growth of the jaw while the brain is growing. If æsthetic considerations and man's interest in faces play some part in creating the demand for orthodontics, the growth of the brain is chiefly responsible for disturbing the orderly process of uniform growth of the jaws from which the dental troubles arise. The chin, which is modern man's peculiar distinction, has probably developed because the growth of the tooth-bearing part is restrained by the long delay in the eruption of his teeth. There has been much speculation as to why this should be so, and it is strange, said Prof. Elliot Smith, that no mention has been made of the fact—clearly emphasised by Dr. H. A. Harris[3]—that the human child until the seventh year, during the pause in his dental development, is growing a phenomenally large brain, and for another 15 years or so, while again he is relatively sluggish in his dental affairs, he is occupied in learning how to put his complicated cerebral instrument to the biological uses essential for human existence. The delay in tooth and jaw development is undoubtedly due to these momentous events, and the salient chin is an index of "mental" development in the psychological as well as the anatomical sense of that term.

This wider vision of the evolution of the face, continued the lecturer, enables us to view in truer perspective many false claims that are repeatedly being made about human tendencies. The reduction in size or absence of the third molar is often said to be a sign that man is destined to lose that tooth in the near future. But in Peking Man, who is supposed by some palæontologists to have lived as much as a million years ago, the third molar is smaller than the others, and the same condition is not uncommon in apes and monkeys. It is in fact a tendency which the whole order of Primates has inherited. Nor, in Prof. Elliot Smith's opinion, does there seem to be any justification for the belief that dental troubles, such as crowding and displacement of teeth and the consequential difficulties, are due to evolutionary changes that are now active. There is no evidence that, apart from the results of racial mixture, any detectable changes are taking place in the jaws and teeth. The same irregularities and deficiencies were occurring 50 centuries ago and contrasts in the form and proportions of the jaws were just as marked. Evolution works with exceeding slowness, and there appears to be no certain evidence, he said, that any effects that can be attributed to recent evolution have yet been detected in modern man's jaws and teeth.

MEASUREMENTS FOR JAEGER'S TEST TYPES.

VISUAL acuity is universally measured by the size of type visible at a distance where accommodation does not come into use. The capacity to read at a short distance depends, apart from visual acuity, on the power of accommodation, and, in the case of myopes, on the degree of magnification which may be present owing to the short focal distance of the unaccommodated eye. For purposes of comparison it is desirable to have a standard of test type for near vision as universally recognised as that of Snellen for distant vision. The editions of Jaeger's type in general use are not quite uniform, although the smallest type is practically always of the same size (0·75 mm. for the height of capital letters and two-thirds of this height for other letters). A pamphlet published by the United States Public Health Service[1] proposes to standardise the size of Jaeger type, beginning at No. 1, as above, and going on with even increases of size by a geometrical gradient to No. 20, with the height of capitals fixed at 25 mm. A uniform standard is obviously desirable, and we think that the proposal of the United States Health Service should be adopted.

THE EPIDEMIOLOGY OF TRACHOMA.

BEFORE Noguchi died in 1927 he was working at a theory attributing trachoma to an organism which he called "bacterium granulosis," and his pupils claim to have confirmed his results. In a general review of the epidemiology of the disease, Mr. A. F. MacCallan[2] opines that until this organism has been isolated in Egypt, the home of the infection, judgment must be suspended. The various countries he divides into four groups, according to the prevalence of the disease. It is practically universal in Egypt, the Levant, Morocco, Algeria and Tunisia, Palestine, Arabia, Persia, and Iraq. It is very common in Italy, Greece, Corsica, Sardinia, Poland, Lithuania, Latvia, Esthonia, Finland, Czechoslovakia, Russia, China, Indo-China, Japan, Argentina, Mexico, and Turkey. It is occasional, with local heavy infections, in Ireland, Holland, Belgium, France, Spain, Portugal, Hungary, Austria, Germany (very local East Prussia), Albania, Jugo-Slavia, Bulgaria, Rumania, Australia (very local), and United States of America (very local, especially among the Indians). It is rare in England, Scotland, Wales, Norway, Sweden, Denmark, New Zealand, and Canada. Four stages of the infection may conveniently be recognised according to the prominence of lymphoid follicles, papillary hypertrophy, and connective tissue formation. Infectivity depends partly on the stage of the disease, the first two stages before cicatrisation has commenced being the most contagious, partly on the presence of an intercurrent acute conjunctivitis, and partly on the state of the conjunctiva of the recipient. No race of mankind appears to be wholly immune. The usual method of propagation is digital, with assistance from infected towels, handkerchiefs, and beds. Infections by flies probably play a part, though this is not proved. It appears that children are much more susceptible to infection than adults. The state of health of the individual appears to have no important connexion with the spread of infection. The increase of the number of infections during the hot months is probably only indirectly connected with the temperature, but directly with the occurrence of epidemics of contagious conjunctivitis due to the Koch-Weeks bacillus or the gonococcus, which in Egypt is not necessarily of venereal origin. In a typical Egyptian village it was found that a quarter of the children were infected with trachoma before the end of the first year of life.

In the presence of dirt, bad housing, and bad water-supply, prophylaxis is almost impossible, but with the opposite conditions much may be done. For Europeans in the East the chief danger of infection is through native servants. In cases already infected, daily treatment by a skilled hand can do much to secure cicatrisation of the trachomatous conjunctiva. The history of the successful fight against trachoma in England is instructive. In 1874, Nettleship found 42 per cent. of the inmates of poor-law schools in London trachomatous. Since the establishment of a special school at Swanley, where all trachoma cases can be treated and educated at the same time, the percentage has rapidly decreased. In 1896 it was 4·9 per cent. At present all infected cases found in any of the L.C.C. primary schools are sent to Swanley. Last year the total number of new trachoma cases was 42. Among the general population in England it is now rare to see a case of trachoma, and when such are seen it is generally in those returned from the East.

SULPHUR TREATMENT OF G.P.I.

THE use of sulphur injections in general paralysis was originally suggested by D. F. Tutunji[1] in 1925, but Knud Schroeder, two years later, was the first to put it into practice. Since Schroeder described his early results in THE LANCET[2] a considerable number of English observers have recorded their experience in these columns. N. G. Harris[3] found that injections of sulphur in olive oil produce high fever, even in patients who have had malarial treatment previously. He regarded the method as safe, simple, and worth trial. W. H. Shilvock[4] was also favourably impressed, but remarked on individual variations in the responses obtained. He thought that the remedy probably acts by causing a focal reaction in areas of chronic sepsis. W. G. Patterson and S. R. L. Switzer[5] did not get such high temperatures as Schroeder with the doses he recommended; indeed, their average was between 101° F.–102° F. J. H. R. Laptain,[6] though pleased with the clinical results, found similar difficulty in obtaining high fever; and this observation is made again in a report from France by C. Levaditi and co-workers.[7] They have treated three cases, and say that the injections were well tolerated and sometimes evoked pyrexias similar to those of induced malaria. This action, however, is described as inconstant, and in none of the patients was any improvement noticed, either clinical or serological. They agree with Shilvock that the reaction varies considerably in different patients. Their first patient attained a temperature of 104° F. on two occasions early in the course; the other two did not reach this figure, which Patterson and Switzer regard as desirable. Yet with all this the mechanism of the remedy remains in doubt, and we welcome the publication of what appears to be the first experimental study of this aspect. R. P. Mackay,[8] of Chicago, after work on animals as well as human patients, tentatively attributes the fever to liberation of protein from muscle tissues which have been damaged by injection of the sulphur or by the irritant hydrogen sulphide. The building up of an immunity to sulphur strongly suggests, he maintains, that the reaction is biological rather than chemical, and he notes that patients in whom it is easy to produce fever by injection of typhoid vaccines also respond well to sulphur, and the contrary. Injection of sulphur suspensions into rabbits produced localised necrosis of muscle and an acute inflammatory reaction; and the facts, as he sees them, seem to place the fever following injections of sulphur on the same basis as that following extensive deep X ray therapy or extensive trauma to living tissue. Though it is too soon to decide on the therapeutic value of the remedy, one may say, Mackay concludes, that "sulphur can accomplish what fever produced by any other method can accomplish, and that by virtue of the long duration of the fever produced sulphur should bring results more rapidly and surely than any other method." At the same time the treatment should not be undertaken lightly, nor in cases where the therapeutic outlook is unpromising.

AVERTIN AND CEREBRO-SPINAL FLUID.

SOME observations on the effect of avertin on th[illegible] pressure of the cerebro-spinal fluid have been ma[illegible] at the Cleveland Clinic Hospital,[9] where this [illegible] has been in routine use for the surgery of neurological patients. The investigators found that, using the dosage of 0·1 g. per kg. of body-weight, there, was an increase in the pressure of the spinal fluid, of about 100 mm. of water, accompanying the narcotic state induced by the avertin injection. After about 15 to 25 minutes the pressure of the spinal fluid was about 50 mm. above the initial reading. It is conceivable that these results may be of practical import to those who combine the use of avertin injection with spinal analgesia. This combination has not, we believe, been very largely employed, but it is extolled by some as warmly as it is condemned by others. The future will, no doubt, assign to it its true value.

INDEX TO "THE LANCET,"

VOL. I., 1931.

THE Index and Title-page to Vol. I., 1931, which was completed with the issue of June 27th, is now in preparation. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 7, Adam-street, Adelphi, W.C.2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

SPECIAL ARTICLES

AN INVESTIGATION INTO MATERNAL MORTALITY AND MORBIDITY

IN THE DOMICILIARY SERVICES OF MATERNITY HOSPITALS.*

By J. M. Munro Kerr, M.D. Glasg., F.C.O.G.,
REGIUS PROFESSOR OF MIDWIFERY IN THE UNIVERSITY OF GLASGOW;

AND

Albert Sharman, B.Sc., M.B. Glasg.,
CARNEGIE RESEARCH SCHOLAR AND SURGEON TO OUT-PATIENTS' ROYAL SAMARITAN HOSPITAL FOR WOMEN, GLASGOW.

A consideration of domiciliary obstetric practice furnishes us with some very important information regarding maternal mortality. The domiciliary services of the large maternity hospitals and maternity units of the general hospitals, the services of such institutions as the Queen Victoria Jubilee Institute, and the records of cases attended by midwives in private practice, published by the local authorities, supply a mass of figures upon which exact calculations can be made. The services undertaken by these agencies differ very slightly as regards the conditions under which the work is carried on. Probably the services of maternity institutions, placed as they are in densely populated industrial areas, deal with the very poorest class, but all minister to individuals in very humble circumstances. On this point only a word or two is necessary. As far as can be judged from the investigations made by individual observers, public health authorities and specially appointed committees, all evidence goes to indicate that environment per se is not a causative factor of any consequence. "Crowded dwellings and dirty surroundings not in themselves increase the incidence of puerperal sepsis." † Similar statements are made regarding food and alcohol. As regards food, we are convinced from cases admitted to hospital that insufficient food and food deficient in certain ingredients or constituents do exert an unfavourable influence on the course of pregnancy and on recovery after labour. Such factors must be predisposing causes to sepsis and obstetric shock, however difficult it may be to estimate their extent.

Our investigations have impressed us with the fact that antenatal care and early recognition of abnormalities are the most important factors in obviating mortality and morbidity.

The Inquiry.

With the object of discovering what exactly are the results in the domiciliary practice of a large institution, we have taken the figures of the outdoor service of the Glasgow Royal Maternity and Women's Hospital for the years 1926–1930, inclusive. To make the analysis of these figures as complete as possible, we have made the following investigations: (1) the fatalities in the district practice of the hospital; (2) the fatalities in the cases transferred from the district to the hospital; (3) the fatalities in cases transferred to municipal fever hospitals, to which all cases of definite puerperal fever are sent; (4) the incidence of notifiable pyrexia in the district practice; (5) the incidence of pyrexia in cases transferred from the district into hospital; and (6) the incidence of death and of pyrexia in cases attended by midwives and by medical students in training.

Before discussing these figures we must explain certain features of the indoor and district services of the hospital. The Glasgow Royal Maternity and Women's Hospital has never discriminated between "booked" and "emergency" cases. Its service has always been at the disposal of all women in pregnancy and labour. Unfortunately, of the district cases attended during the five years under review, only about 27 per cent. have attended our antenatal clinic. In recent years not only has the accommodation of the hospital (at present 175 beds, inclusive of 23 in isolation block) been taxed to the utmost, but there has been a steady increase in the number of indoor abnormal cases. This is evident from Table I.

Table I.—*Percentage Abnormalities in Indoor and Outdoor Services of the Hospital.*

Year.	Indoor.		Outdoor.	
	Total cases.	Percentage abnormal cases.	Total cases.	Percentage abnormal cases.
1926 ..	3653	58·3	3594	16·6
1927 ..	3902	60·1	3538	19·4
1928 ..	3941	62·4	3797	17·6
1929 ..	3841	68·9	3820	7·5
1930 ..	4469	70·1	4079	8·9

As indicating the extent of the indoor operative work, we find that during the years under review there were 659 Cæsarean sections, 419 cases of placenta prævia, and 546 cases of accidental hæmorrhage.

As regards the district practice, there has been a steady fall in the number of cases operated upon outside, although the total number of cases attended has increased. This is clearly indicated in Table I. It is accounted for by the fact that in recent years operations of any gravity have been discouraged; only the simpler abnormalities are treated in the patients' homes. As far as possible we transfer to the hospital all cases in which any difficulty in the delivery is obvious or anticipated.

The organisation and technique employed has not varied. The patients have all been attended by medical students or nurses in training. If any abnormal condition is detected, or should delay in the labour occur, the outdoor house surgeon is summoned. He, in turn, can appeal to one of the members of the indoor staff. For the cleansing of the attendant's hands and of the patient's vulva, soap and water and lysol have been employed. We have now substituted for lysol the routine use of biniodide of mercury. The nurses wear aprons, but neither masks nor gloves. The students wear gloves.

Table II. indicates the relative incidence of sepsis in students' and nurses' cases in the outdoor department. It will be noticed that cases of puerperal sepsis have been subdivided into pyrexia and fever for the year 1930 only, the reason being that this year was the first complete one for which exact figures for pyrexia and fever separately could be obtained from the local health authority. The increased recorded incidence of sepsis during the years 1929 and 1930 is probably due to the introduction of new notification regulations, and the consequent more complete and accurate notifications.

---

* Based on the district practice of the Glasgow Royal Maternity and Women's Hospital from 1926–1930, inclusive.

† Interim report of Departmental Committee on Maternal Mortality and Morbidity, par. 77, London, 1930.

Throughout this investigation we have used as the standard of morbidity that of the Department of Health (Scotland)—namely, the occurrence within 21 days after childbirth or miscarriage of a febrile condition in which a temperature of 100·4° or more has been sustained during a period of 24 hours or has recurred during that period. We have referred to the fact that students wear gloves and the nurses do not wear gloves. To this, and to the fact that the former are possibly more imbued with the "antiseptic spirit" or conscience, we attribute the lower incidence of sepsis in cases attended by students. The very low incidence of deaths and sepsis in students' cases compares favourably with the very best figures yet published—e.g., East End Maternity Hospital, London, where morbidity for district cases in 1928, 1929, and 1930 averaged 0·34 per cent. In this institution only "booked" cases are attended. The nurses wear no gloves, and they trust entirely to very thorough disinfection with perchloride of mercury. We are of opinion that the use of gloves is advisable as an additional protection to the patient, and that it is a protection to the attendant. The cost of gloves per patient, indoor and outdoor, works out at approximately 2*d*. per patient treated.

TABLE III.—*Puerperal Sepsis in Cases Delivered on District.*

Year.	IN "NORMALS."			IN "ABNORMALS."		
	Total cases.	Cases of sepsis.	Percentage morbidity-rate.	Total cases.	Cases of sepsis.	Percentage morbidity-rate.
1926 ..	2,998	39	1·3	596	8	1·3
1927 ..	2,852	25	0·8	686	6	0·8
1928 ..	3,129	23	0·7	668	8	1·2
1929 ..	3,534	38	1·0	286	9	3·1
1930 ..	3,716	41	1·1	363	8	2·2
—	16,229	166	1·0	2599	39	1·5

Tables III. and IV. indicate the total deaths and cases of pyrexia which occurred on the district. Of the 15 non-septic cases, 1 died undelivered, 3 died partially delivered, 5 of "obstetric shock," 2 of pneumonia present during labour, 1 under anæsthesia, 1 after removal of adherent placenta, 1 after forceps delivery, and 1 from cardiac failure on the tenth day of the puerperium. The following are very brief particulars of the most interesting cases.

(1) Twins: no interference; collapse several hours later: obstetric shock. (2) Normal; no interference except placenta expressed; some hours later found dead; obstetric shock. (3) Found dead when first seen, baby being born to shoulders; labour said to have been precipitate and painless; ? acute cardiac failure or obstetric shock. (4) Breech; as doctor tried to deliver head patient died, before delivery. (5) Baby born spontaneously before nurse arrived; patient died same day, no apparent cause. (6) Patient died as doctor arrived; ante-partum hæmorrhage: undelivered.

TABLE IV.—*Total Maternal Deaths from all Causes in Cases Delivered on District.*

Year.	Total cases.	DEATHS IN CASES DELIVERED ON DISTRICT.				
		Cases of sepsis.		Non-sepsis.	Total.	Maternal mortality-rate from all causes (per 1000 cases).
		In "normals."	In "abnormals."			
1926	3,594	7	2	1	10	2·7
1927	3,538	6	0	3	9	2·5
1928	3,797	6	0	4	10	2·6
1929	3,820	3	2	2	7	1·8
1930	4,079	3	4	5	12	2·9
—	18,828	25	8	15	48	2·5

We must now add the cases transferred to the hospital from the district and treated in the hospital. These are shown in the next Tables (V. and VI.). Table VI. includes both categories tabulated in Tables IV. and V.

TABLE V.—*Deaths in Cases Transferred to Hospital.*

Year.	Cases.	Total deaths.	Deaths per 1000 cases.
1926	166	9	54·2
1927	143	6	41·9
1928	109	5	45·8
1929	133	6	45·1
1930	141	6	42·5
Totals ..	692	32	46·2

TABLE VI.—*Total Maternal Deaths in District Cases, including those Transferred to Hospital.*

Year.	Total cases.	Total deaths.	Maternal mortality-rate per 1000 cases.	Maternal mortality-rate in Scotland per 1000 cases.
1926 ..	3,760	19	5·0	6·4
1927 ..	3,681	15	4·0	6·4
1928 ..	3,906	15	3·8	7·0
1929 ..	3,953	13	3·3	6·9
1930 ..	4,220	18	4·2	6·9
Totals	19,520	80	4·09	6·7

(Maternal mortality-rate statistics for Scotland, according to the Department of Health, are not strictly comparable with those for other countries, owing to different methods of classification.)

We must now analyse the cases operated upon on the district (Table VII.).

Unfortunately, as regards Table VII. we have not been able to extract exact figures as to the number of occasions on which each of these operations were performed, but we have been impressed with the high proportion of cases which developed pyrexia when the placenta was removed manually. It is a striking fact that the only death from sepsis followed this operation.

We must now consider the incidence of death and pyrexia in cases transferred to the hospital from the district. The total district cases were 19,520, of which 692 were transferred to hospital. It is therefore with these 692 cases we have now to deal. Table VIII. is a summary of these cases.

TABLE VII.—*Details of Operations Performed on the District and followed by Sepsis.*

Year.	Total No. of operations.	Sepsis following operations.	Nature of operation.			
			Manual removal of placenta.	Forceps.	Curettage.	Suturing.
1926	454	4	3	1	—	—
1927	521	3	2	1	—	—
1928	501	6	6	—	—	—
1929	446	6	2	3	1	—
1930	208	5	3	1	—	1

TABLE VIII.

—	Deaths (32).		Pyrexia (68).
	Sepsis.	Non-sepsis.	Total cases.
Obstetrical complications..	6	5	38
Toxæmias	—	6	4
Ante-partum hæmorrhage:			
Placenta prævia ..	1	2	11
Accidental hæmorrhage	—	7	1
Post-partum hæmorrhage..	—	—	4
Abortion (and mole) ..	2	2	8
Cardiac	—	1	1
Debility	—	—	1
Totals	9	23	68

(The pyrexia-rate in these cases is 9·8 per cent.)

When a further analysis of these cases is made, we find they divide themselves into three groups: (*a*) Cases which died undelivered; (*b*) cases in which spontaneous delivery occurred; (*c*) cases in which operative treatment was necessary.

(*a*) CASES WHICH DIED UNDELIVERED.

There are six cases in this category. These patients only lived a few hours, some only a few minutes, after admission. Death in four cases resulted from accidental hæmorrhage, in one case from spontaneous rupture of uterus, and in one case from cardiac disease.

The high death- and pyrexia-rate shown in Table IX., 3·4 per cent. and 6 per cent. respectively, in spite of the fact that the delivery was spontaneous, is very striking.

It will be observed that in 9 of the 11 fatal cases death was due to eclampsia, accidental hæmorrhage, or yellow atrophy, and that 6 of the 19 cases of pyrexia were associated with those complications. This emphasises the importance of toxæmias as a cause of death and pyrexia.

Table X. shows a 4·06 per cent. mortality-rate and a 13·2 per cent. morbidity-rate in operative cases transferred from the district. This unselected operative group, illustrative of cases requiring institutional treatment, represents the grave cases one might expect to encounter in ordinary domiciliary practice. But had all these cases received close antenatal care, mortality and morbidity would have been enormously reduced.

We have, with the assistance of Miss Duff, our almoner, traced the total district cases which received antenatal care during these years, and, as already stated, found that they numbered only 27 per cent. of those attended. In analysing the deaths, we have been able to get exact information only regarding those district patients who were admitted to hospital and died there—32 in number. Of these only 5, or 15·6 per cent., had attended the antenatal clinic in the later weeks of their pregnancy.

It is of interest at this point to compare the mortality incidence in indoor cases which had antenatal supervision with those which had not. The death-rate over four years in the former category averaged 1·2 per cent. of admissions, as compared with 3·6 per cent. in the latter category.

Reports from Elsewhere.

In order to make our investigation of "district" midwifery a wider one, we have studied the 1926–1930 reports of several of the larger maternity hospitals and obstetric units of general hospitals in Britain,

and we are particularly indebted to the obstetric registrars of Queen Charlotte's, Guy's, St. Mary's (Manchester), and Liverpool maternity hospitals for their courtesy and assistance. Unfortunately, from none of the hospitals have we been able to extract figures exactly comparable over the five-year period.

As regards Queen Charlotte's Hospital, the total district cases attended for the years 1926–1930 numbered 8138, with four deaths and 321 cases of morbidity (3·9 per cent.). As the standard of morbidity used in these cases was "a temperature of 100° in the first ten days," a standard other than that of the Department of Health (which we employed), it is inappropriate to compare our figures. In that hospital district work is not done by students but by nurses and, until this year, neither gloves nor masks were worn by them. Lysol is the antiseptic employed.

In Guy's Hospital, the cases delivered on the district are not indexed separately from those delivered in the institution (from the hospital area), and consequently mortality- and morbidity-rates are composite for both categories. A temperature of 100·4 F. or more, sustained during a period of 24 hours or recurring during that period, has been used as the standard in calculating morbidity. In 1928, the morbidity-rate was 4·6 per cent.; in 1929, 4·1 per cent., and in 1930, 3·7 per cent. In Guy's service the wearing of gloves is optional, but is usual with students. The antiseptic employed is perchloride of mercury.

In the district service of St. Mary's Hospital, Manchester, gloves are only worn for instrumental deliveries, and the antiseptic used is biniodide or perchloride of mercury. During the earlier part of 1926, lysol was employed, and it is interesting to note that the puerperal sepsis-rate during that year was considerably higher than in subsequent ones. During the years 1926–1930, 6496 district cases were attended, with 6 deaths and 18 cases of puerperal sepsis. The B.M.A. standard of morbidity has here been employed, and this, together with the fact that district cases transferred to hospital are classed with hospital cases, has rendered a comparative analysis of their results with ours impossible.

The total number of district cases attended by Liverpool Maternity Hospital during the years of survey amounted to 7615. Figures of maternal mortality and morbidity for each of these years are not given in their reports, and there are no special statistics dealing with outdoor cases transferred to the hospital; consequently we cannot compare their results with ours. During the years 1928, 1929, and 1930, the district maternal mortality was nil. Both students and nurses wear gloves, and the antiseptic used is perchloride of mercury.

Conclusions.

We have investigated nearly 20,000 consecutive cases in the district practice of a large maternity hospital, including a "follow-up" of all the cases of puerperal sepsis. Impressed with the analysis of the figures we have reached certain conclusions.

(1) We consider the low figures for pyrexia in the outdoor work satisfactory.

(2) We are gratified to find that the results of the work carried on by medical students and midwives in training stand favourable comparison with those of the domiciliary midwifery services of other institutions and nursing organisations.

(3) It is our opinion that district morbidity can be further reduced, and that the routine use of gloves by pupil midwives and students, and the employment of biniodide of mercury, will assist materially in achieving this. We also advocate the wearing of a mask.

(4) We have been impressed by the fact that, in spite of the unfavourable conditions of district hospital practice, a simple antiseptic ritual appears to be sufficient.

(5) While not wishing to minimise the importance of sepsis as the primary cause of puerperal deaths, we would emphasise the important rôle of non-septic factors as causes of maternal mortality. The 15 deaths on the district from non-septic causes are illustrative of this; some represent probably the non-preventable accidental fatalities of childbirth. A number are stated, however, to have died of "obstetric shock" or collapse; this grave problem is receiving considerable attention at the present time.

(6) Our figures indicate that the morbidity-rate of the district service is lower than that of the indoor service in normal cases. One must, however, in making such a comparison, take into consideration the fact that the recording of temperatures is more complete in hospital than on the district. It would appear, therefore, that, judged from the purely medical point of view, there is no necessity for the general hospitalisation of uncomplicated cases. On the contrary, there appears to be a certain danger in housing normal with complicated cases. There can be little doubt, however, of the importance of transferring to an institution all cases requiring operative treatment.

(7) In common with others who have undertaken investigations into maternal fatalities, we are impressed with the high death-rate in women who had received no adequate antenatal care. As far as we can judge, the most striking immediate improvement in puerperal mortality and morbidity would be effected by the extension of antenatal care. It is most disappointing to find that the proportion of women seeking antenatal attention is so low (27 per cent.); further, that in the years under review it has remained stationary—viz., 1926, 29 per cent.; 1927, 25 per cent.; 1928, 25 per cent.; 1929, 27 per cent.; 1930, 28 per cent. It is to this aspect of the question that attention should be concentrated, in order to secure immediate improvement in maternal mortality and morbidity.

We desire to thank the Public Health Department of the city of Glasgow for their valuable assistance.

IMPERIAL SOCIAL HYGIENE CONGRESS.

AT a medical session on July 14th, at which Dr. DAVID LEES took the chair, a discussion on the

Choice of Remedies in Syphilis

was opened by Colonel L. W. HARRISON. In early syphilis, he said, his goal was 100 per cent. eradication of infection in every case. Other things being equal, he preferred the original 606 because it hit the spirochæte harder and longer than did 914, but unfortunately its reactions deterred many patients. Whichever arsenical drug was most convenient could be used, with a change to a different drug for the second course if the results had not been good at first. He believed in giving large doses and reducing the toxic effects to a minimum, rather than risking inadequate results for fear of consequences. The greater the individual dose, the better the immediate result. Encephalitis could be avoided by commencing the dosage cautiously and testing the patient's tolerance. Dermatitis would give no trouble if earnest attention were paid to the least sign of skin lesion and sodium thiosulphate were used promptly. A deposit of arsenobenzol in the skin often caused sensitisation, with increased liability to dermatitis at a later date; therefore care should be taken to enter the vein and if, by any chance, the needle missed the vein, another vein should be selected at once. Jaundice was a more troublesome complication, for it was tantalising and followed no rules. It was never seen in the female and seemed to occur in outbreaks. There was some evidence that it was related to fasting; it was very rare among private patients, who usually ate a good deal of fat. Recent experiments by Craven suggested that it was wrong to make the patient eat a great deal of carbohydrate, and that the seasonal variation was related to a reduction of fat at certain seasons.

The choice of a bismuth preparation was far from easy, and depended on whether the bismuth was to play the principal part in treatment or only to serve to keep up a concentration between courses of other drugs. For the first purpose the preparation must be absorbed quickly and in sufficient amount to give an adequate concentration in the tissues. Too small a concentration might have a provocative effect, but the amount to be dealt with in one day must not throw too much work on the kidney—i.e., it should not be more than 10 mg. For this reason small doses should be given two or three times a week. If the bismuth were to be only an adjuvant the preparation should be absorbed slowly, but the compound must give up its bismuth ion. Intramuscular injection had a higher therapeutic index and margin of safety than intravenous; the latter route presented the drug so suddenly that toxic effects were likely to supervene. Watery preparations were the most rapidly absorbed; they were said to be more painful than others, but this defect could be obviated by administering them with a local anæsthetic. They must be given two or three times weekly. Oily preparations were absorbed evenly and regularly but more slowly, and therefore made a less violent assault on the excretory mechanism. They were actively spirochæticidal, but must be given twice weekly. The insoluble preparations of choice were the oxychloride in watery medium (which the speaker preferred), the finely divided metal, and the salicylate; the fineness of the subdivision was undoubtedly a factor in the therapeutic power. These preparations were used when the patient's tissues were to remain saturated between two courses of another drug. The fear was that absorption would be too slow.

Mercury should only be used where bismuth was impracticable, for as a rule it was impossible to obtain the necessary concentration in the tissues without going over the edge of toxicity. For oral use he preferred the yellow iodide or calomel, the absorption of which was proportional to the dose. Metallic mercury should not be used. The oral route should, however, only be followed when circumstances prevented other methods. For injection a watery solution given intravenously daily or on alternate days was the best, but there was no point in giving it if bismuth was available. On the whole calomel was the best preparation for regular absorption and activity, but it caused some pain, which could be overcome by local anæsthesia. When it could not be tolerated a cream of not more than 10 per cent. concentration should be used. The site of injection should be thoroughly massaged. For such patients as migrants, for whom bismuth treatment was impossible, mercury by the mouth was useful; the perchloride or iodide should be used rather than grey powder and a concentrated ointment given for inunction.

Late syphilis presented a very different problem: that only of keeping the spirochætes in check. In this stage mercury might be valuable, because it prevented the reaction of the tissues—in late syphilis the patient was often killed by his own defences. If the cerebro-spinal fluid gave a positive reaction there was little hope of changing it after two years. Early pyrogenetic treatment should be given, combined with tryparsamide. Malarial centres should be organised for these patients.

DISCUSSION.

Dr. A. R. Cook said that in Uganda there was some doubt of the efficacy of 606, and referred to Dr. J. H. Sequeira's papers.[1] Extraordinarily few cases of tabes and general paralysis were seen in natives of Uganda, although syphilitic hemiplegia was relatively common and there had been a decided increase of cardiovascular syphilis. Mercury and bismuth were given concurrently with arsenical preparations. The Bagandi had been a slowly dying race, though head and shoulder above other natives in physique; an intensive propaganda against venereal disease, and an antenatal and child welfare campaign had therefore been started to counteract the decrease in population. Mercuric chloride by the mouth had been selected as a cheap, popular large-scale method and had attained an enormous vogue, with striking results among the pregnant women. Babies were born healthy, and congenital syphilis was much less common than it had been.

Dr. James McIntyre said that insoluble preparations had been found most satisfactory in County Durham. A lowered standard of nutrition had resulted in an increase of jaundice during arsenical treatment; dosage had been reduced and bismuth partially substituted.

Lieut.-Col. E. T. Burke said that a great deal of under-treatment was going on in this country. He thought intravenous administration of bismuth absolutely contra-indicated. Thorough treatment by mercury might have tragic results on the patient; the drug should not be used when bismuth and arsenic were available and its value was that of an adjunct only. A pyrogenetic centre had been established in Salford to put up a "malaria barrier between the clinic and the mental hospital."

Lieut.-Col. J. J. Harper Nelson described cases of arsenical neuritis seen in Lahore as a consequence of misuse of modern preparations. He had only seen two cases of tabes and one case of general paralysis in 12 years. Two of these three patients had had European blood. Possibly natives had been immunised by previous malaria. The commonest form of nerve syphilis was syringomyelitis, and the commonest circulatory lesion was aortitis.

Dr. Nora Wattie urged the hospitalisation of acute cases, with frequent small doses at the beginning of treatment. Complications seemed to occur in the later courses rather than the first.

Dr. A. O. Ross remarked on the great number of patients with primary syphilis who showed electrocardiographic change although they had no clinical signs of cardiac syphilis. He had seen a great deal of neurosyphilis in Europeans who had had malaria.

Dr. Myrtle Noronha suggested that lack of treatment in the early stage might account for absence of neurosyphilis in natives, the virus having burnt itself out before the "neuro" stage arrived.

Dr. Louise Pearse agreed that this might be so, and mentioned experimental evidence in support.

---

[1] THE LANCET, 1930, i., 159, 723, and 1328; 1931, i., 57.

She agreed that 606 was a more effective therapeutic agent than 914.

Dr. A. G. **Coia** emphasised the rarity of tabes and general paralysis in the tropics and said that in British Guiana the treatment had been very unsatisfactory in the past; patients had probably died of other syphilitic complications before they had had time to develop neurosyphilis.

Dr. **David Lees** described cases of sensitisation to arsenobenzol preparations among the nursing staff. Attempts to desensitise had caused acute anaphylactic reactions and in one case death, although there had been no question of the presence of these substances in the tissues. He also referred to the production of aplastic anæmia by these drugs. He did not think that arsenobenzol was the sole cause of jaundice. Alcohol during treatment was certain to produce some type of intolerance. He relied chiefly on the arsenic to stamp out the spirochæte, the bismuth being accessory. There were few cases of intolerance so long as the hygiene of the mouth was attended to, and there should be a dental clinic associated with every venereal disease centre. He did not agree with the doubts expressed by Dr. Sequeira about 606. Malaria was undoubtedly the best pyrexial agent at present available, but it was time to seek for some other method. Pyrotherapy alone, however, was in most cases only alleviating; it must be supplemented by arsenic and preferably by tryparsamide.

Colonel **Harrison**, in reply, said that not a scrap of evidence had been found to indicate that modern treatment encouraged neurosyphilis. The incidence might be a question of soil rather than of seed. The average European stopped his malaria with quinine and therefore might develop neurosyphilis in spite of having been in malarious countries. Europeans infected by native women were just as much affected as others.

Dr. **Gladys Sandes** opened a discussion on

Methods and Results of Dealing with Antenatal Venereal Diseases.

She analysed 1000 consecutive deliveries from the maternity department of the London Lock Hospital since 1920, and also 34 from the Highbury Hostel attached to the Royal Free Hospital. She concluded from her analysis that syphilis acquired after the fifth month of pregnancy ought not to affect the child so long as the mother was rendered non-infective before delivery; even so, she should not be allowed to breast-feed the child. No special abnormalities were observed during labour or puerperium in treated cases. Gonorrhœa might shorten the second stage of labour and at the same time predispose to rupture of the perineum if the soft tissues had been softened by hot baths and douches during treatment. Puerperal complications were rare. In nearly every case of ophthalmia there had been early rupture of the membranes, prolonged labour, or only a small amount of antenatal treatment for the mother's gonorrhœa.

So long as sufficient time was given to treatment the results seemed to be satisfactory whatever method was used. Pregnancy did not affect the technique of treatment for gonorrhœa, except that douches were given more slowly and at a lower pressure, and, of course, intracervical swabs could not be used. The syphilitic woman should have at least one course of arsenobenzol compounds before delivery. Ideally she should have six weekly injections of 0·6 g. novarsenobillon or its equivalent; an injection of 0·125 g. contramine after the fifth and seventh injections was especially useful for patients likely to react unfavourably to arsenic. A course of bismuth should be given afterwards, or concurrently. Mercury injections were usually painful to pregnant women, but pills could be given in the later half of pregnancy. Bismuth injections were non-painful, efficient, and very safe. If the W.R. came down to plus 30 before delivery, the baby would probably be free of disease; if it was plus 120 or plus 240 the baby would probably be a congenital syphilitic. Any mother who had syphilitic changes in her cerebro-spinal fluid would almost certainly bear a syphilitic baby. The incidence of congenital syphilis was due primarily to the absence or inadequacy of treatment during pregnancy, and therefore an educated public opinion was obviously of great importance in its eradication.

The Elsie Inglis Memorial Hospital.

Dr. **Mary Macnicol** described methods and results at this Edinburgh hospital, where there was a ward *for ten patients and two out-patient clinics*. She emphasised the importance of having wards and clinics for cases of venereal disease attached to every maternity hospital. Amazingly good results followed the effective treatment of syphilis, but the prognosis in gonorrhœa only justified humility and a dogged determination to "make the best of a bad job." It was extremely important to take a blood test from every pregnant woman and to give treatment in every subsequent pregnancy to a woman who had ever had syphilis. Even partial treatment was of great value. The full course given was six weekly injections of 0·3 g. N.A.B. intravenously, and then one monthly injection of 0·45 g. A mixture of grs. 10 of potassium iodide and ʒi of liq. hyd. perchlor. was given thrice daily. Sulfarsenol was given intramuscularly in some cases, but the women preferred the intravenous injections. Bismuth was reserved for the interval between pregnancies to avoid strain on the kidneys.

In Dr. Macnicol's view the only satisfactory as of the treatment of gonorrhœa was the preven of ophthalmia neonatorum. The danger to th child from antenatal gonorrhœa had been large removed, but the mother ran the threefold risk puerperal infection, later chronic cervicitis, end metritis or salpingitis, and subsequent sterility. It was important to avoid the use of instruments for induction or during confinement and to avoid all lacerations of the birth passage. At the Elsie Inglis Hospital the cases were carefully followed up, and the impression was held that careful antenatal treatment did much to prevent postnatal complications. Lactic acid, mercurochrome, and glycerin had been found the most useful drugs, and vaccines were being used increasingly. No douching or swabbing was done for the first ten days after the birth, but free drainage was encouraged by raising the head of the bed. Where induction was necessary and drugs could not be used, the membranes were manually separated and the vagina packed with gauze soaked with mercurochrome.

An interesting paper by Dr. G. G. **Butler** and Dr. G. M. L. **Summerhayes** discussed antenatal yaws and syphilis in Accra, Gold Coast.

Dr. **David Nabarro** read a paper on the prevention of inherited syphilis by treatment of the mother. He mentioned special Swedish hospitals for syphilitic mothers, and said that 20 beds at St. Margaret's Hospital had now been set aside for the residential treatment of pregnant women.

Dr. **Margaret Balfour** and Dr. **Myrtle Noronha** communicated papers on the antenatal treatment of syphlis and the care of the syphilitic mother and child in India, and a brief discussion followed on the advisability of subsidising government hospitals for this purpose.

THE BRITISH EMPIRE CANCER CAMPAIGN.

THE YEAR'S PROGRESS.

THE annual general meeting of the Campaign was held on July 20th at the House of Lords, Lord Reading presiding. The annual report consists of a substantial volume of some 200 pages, mostly made up of accounts submitted by subsidised institutions and individuals of the progress achieved during the year under review. The usual foreword, signed by Lord Reading as chairman of the Grand Council, drawing attention to certain results obtained, has this year an added value, in so far as it is supplemented by page references to the fuller accounts by the actual observers.

Notes on the extensive experimental, clinical, and pathological investigations on the action of radium and X rays, which are being actively pursued in many centres, take up a considerable part of the annual report. Apart from these, among the more outstanding contributions made to the cancer problem by workers connected with this Campaign, the progress of which has not recently been recorded in our columns, are the production of cancer by a pure chemical substance (see p. 197), the detoxication of carcinogenic mineral oils, and the demonstration of hereditary factors in certain forms of cancer in humans.

DETOXICATION OF MINERAL OILS.

In Manchester, under the direction of Dr. C. C. Twort, special attention has been given to the investigation of the causes of mule spinners' cancer, and especially to the cancer-producing properties of mineral oils and the possibility of removing harmful compounds from them in such a manner that they can be used commercially without increasing their cost or diminishing their lubricating qualities. Investigations on the effect of the treatment of mineral oils with sulphuric acid indicate that though a very large quantity of acid must be used in order completely to detoxicate carcinogenic mineral oils, smaller amounts such as 10 per cent. by volume are capable of materially lessening the potency of lubricating oils. The committee recommend that the owners of mills should mix into their lubricating oil the necessary quantity of sperm oil or lanolin, and preferably use mineral oil which is as far as practicable saturated. The practical utility of other methods of detoxication, such as exposure to ultra-violet light and radon, appears to be doubtful.

THE HEREDITARY FACTOR IN POLYPOSIS INTESTINI.

At St. Mark's Hospital special attention has been directed to the disease known as multiple adenomata, multiple papillomata or polyposis intestini, a condition in which the mucous membrane of the colon and rectum is studded with adenomatous epithelial proliferations.

Investigations have shown that polyposis intestini is an inheritable disease which is transmitted by both males and females, that both males and females suffer from the disease, and that the inheritance can be traced through several generations. If members of these families survive the other complications of polyposis and ordinary risks of life, they develop cancer of the rectum or colon, usually in the early thirties or forties.

THE EFFECT OF IMMUNE SERA ON CANCER CELLS.

In the Cancer Research Laboratory of the London Hospital, Dr. T. Lumsden has tested a large number of different drugs, bodily secretions, radiations, and other reagents such as heat and cold, on tissue cultures of cancer cells and of normal cells. The only reagent he was able to produce which killed cultured cancer cells without damaging normal body cells seriously, was an antiserum produced by inoculating into an animal the cancer of a different species of animal and then testing this antiserum upon tissue cultures made from a third species of animal. Unfortunately, however, attempts to apply these results in treating cancerous mice failed, for the antiserum could not be injected in a degree sufficiently concentrated to destroy the cancer without causing the death of the mouse. However, such sera can be separated into fractions of which one fraction contains practically all the anticancerous elements in the serum and is much less toxic when inoculated into living animals than the original anti-cancer serum from which it was made. When an implanted tumour is destroyed by inoculating this refined anti-cancer serum into it, gradual reabsorption of the tumour cells occurs and during the process the tumour-bearing animal is rendered immune to recurrences. It is stated that preliminary results of treating mouse cancer, both implanted and spontaneous, raise the hope that ultimate success may be achieved along this line of inquiry, but at the moment consistently good results cannot be achieved. Treatment by anti-cancer serum is not at present applicable to human tumours.

X RAYS AND RADIUM.

X rays and radium have been used not only in experimental therapeutics and in the attempt to discover the way in which they act on biological material, but also to test the nature of the material on which they act. For example, among the pathological investigations at the Middlesex Hospital, the destructive effects of β-radiations upon the following bodies have been examined: the infective agent of the Rous sarcoma, the bacteriophage, several types of pathogenic bacteria, some ferments, antibodies, and toxins. The results appear to indicate that the Rous sarcoma agent is not of the nature of a ferment; they do not, however, exclude the possibility that it may be a non-living agent of complex-protein nature somewhat similar to certain toxins.

Among the inquiries pursued in the radiological research laboratories of this hospital are those on the physiological effects of penetrating X rays on animals; the scattering effects of X rays and Gamma rays in different media; and the reactions of the tissues under different degrees of filtration of radium rays. The best filter for all purposes is held to be platinum. At St. Bartholomew's Hospital the effects of radium on the cerebral tissues of the rabbit are being studied by Dr. E. A. Carmichael and Mr. J. Paterson Ross. Radon seeds inserted within the dura mater, radon seeds placed upon the dura mater, and radium needles placed upon the dura mater were the methods investigated. In discussing the clinical problem of treating cerebral gliomata with radium, it is noted that the greatest problem in treating a brain tumour with buried radium is the difficulty of determining the extent of the tumour. In dealing with tumours in other parts of the body it has been found that it is only when the radium can be placed accurately around the growing edge that satisfactory results are obtained. It is so seldom possible to achieve this accuracy in the brain that, it is said, some alternative method may have to be employed, perhaps distance irradiation. It would appear, however, from the reports of workers at the Westminster Hospital, on results obtained with the four-gramme bomb, that this is unlikely to be the method of election in applying distant radiation. Prolonged treatment by this means causes pathological changes in the blood. Histological examination revealed gross damage to spleen, kidney, and lung in every case coming to post mortem after considerable "bomb" treatment, while not a single "bomb"-irradiated cancer could be regarded as cured when examined under the microscope, though several cancers of the breast and uterus had been demonstrated to be comparatively inactive after treatment with needles.

Dr. Warnford Moppett, working in the University of Sydney, has continued his investigations into the biological effects of homogeneous beams of X rays. He has completed studies (*a*) in relation to a phenomenon termed antagonism, (*b*) in relation to the area of tissue radiated, and (*c*) in relation to time. The phenomenon termed antagonism implies a neutralisation between different components of mixed radiation in their biological action. This was deduced from the fact that the allantoic membrane of the chick is about 1000 times more sensitive to homogeneous radiation than to mix radiation. Dr. Moppett has devised a new type of X ray tube, made of metal, with which it is possible to obtain a more homogeneous beam of X rays with a wave-length approximating to the K discontinuity of radium.

Observations of considerable interest have been made by Miss D. Goulston, also working at Sydney, who has applied the radiations from radium to the chorio-allantoic membrane of the chick embryo. When this membrane is irradiated through a window cut in the shell, a pure hypertrophy of the membrane is produced, not uniformly, but in situations determined by the shape of the opening in the shell. Further, in irregular situations, extraordinary hypertrophy of the endoderm, leading to the formation of papillary tumours, multiplication of the ectoderm leading to apparent patchy epitheliomatous structures, and areas of intense hæmopoieses occur. The results of experiments suggest that these results are not due to the gamma radiation from the needles but possibly either to a modified radiation of longer wave-length, or an action due to secondary waves originating from the components of the shell.

These few samples of the work being done show the activity of the Campaign not only in this country but in its branches and affiliated organisations in the dominions. This report indicates more clearly than any of its predecessors the range and growth of the problem and should stimulate a generous measure of public support.

THE BRITISH PHARMACEUTICAL CONFERENCE.

THE conference met this year at Manchester on July 21st and 22nd. The chairman, Mr. J. H. FRANKLIN, in his address made allusion to the industrial depression in Lancashire and to the possibility that scientific research may provide a solution of the pressing problems of the day; Manchester was associated with the names of many famous men of science, notably Joseph Priestley, Thomas Priestley, John Dalton, and James Prescott Joule.

More than 20 papers were contributed in the Science Section, some of which are here summarised.

POTENCY OF DIGITALIS TINCTURES.

In a paper from the Pharmacological Laboratory of the Pharmaceutical Society on the Variations in Potency and Total Solids of Tincture of Digitalis, Mr. FRANK WOKES said that some analysts had gone so far as to suggest limits of total extractives for tinctures of potent drugs whose active principles cannot yet be determined chemically. He showed the danger of such procedure by means of data obtained on tincture of digitalis; examination of 100 different commercial tinctures showed that there was no definite relationship between the potency and the total solids. The biological assays were all done by the cat method. During the same period in which the 100 commercial tinctures were examined, 24 different samples of digitalis leaves were assayed by the cat method. Eighteen of these samples were British grown and six foreign. The potency of the commercial tinctures ranged from 49 to 200 per cent. of that of the standard tincture and the 24 different samples of digitalis leaf showed a smaller range of potency (63 to 156 per cent. of that of the international standard digitalis powder), but practically the same average potency as that of the 100 tinctures. If percolation is efficient no satisfactory sample of leaf should yield a tincture weaker than about 60 per cent., and English leaves will, in most cases, give tinctures more potent than the standard tincture.

TESTS FOR ERGOT ALKALOIDS.

In collaboration with Mr. H. CROCKER, of the Department of Inorganic Chemistry, Liverpool, Mr. WOKES also contributed a paper on Biological and Spectroscopic Tests on Ergot Alkaloids. The authors gave an account of an attempt to apply the spectroscope to the assay of ergot alkaloids. Parallel tests on solutions of the alkaloids by both biological and spectroscopic methods had shown that they cannot be relied upon to give the same results when estimating the activity of either fresh or deteriorated ergot preparations. Hence the spectroscope could not replace the biological method.

THE SOLUBILITY OF CALCIUM.

Mr. H. BRINDLE (Pharmaceutical Department, Manchester University) dealt with the problem of solutions of calcium, and described a process for the extemporaneous preparation of this product. Calcium lactate is now preferred by many prescribers when a calcium salt is required. It is frequently prescribed in mixtures, and because of the varying solubility of the commercially available article, a clear solution or a mixture containing varying amounts of calcium lactate in suspension may result when the same prescription is dispensed with different samples of calcium lactate. Some prescribers attempt to overcome the difficulty by ordering *Calcii lactas recens.* Since none of the standard text-books consulted gives any information on the method to be adopted, Mr. Brindle's process fills a gap.

The same author contributed a paper on the Volumetric Assay of Lactic Acid B.P. The work therein described was undertaken because a subcommittee of the Pharmacopœia Commission have suggested some modifications in the official process.

FRENCH TINCTURE OF IODINE.

Mr. J. M. WALMSLEY (laboratory of Messrs. J. Woolley, Sons and Co.) referred to a statement in the report of the Pharmacy Subcommittee to the Pharmacopœia Commission, that a new preparation of iodine is required corresponding to the so-called "French tincture of iodine. There was said to be a demand from the medical profession for a solution for the exhibition of free iodine which does not contain any iodine in combination, since it was held that solutions containing iodides were more liable to give rise to iodism than a solution containing iodine alone. Experiments carried out by Mr. Walmsley on a sample of the proposed French tincture of iodine showed that during three months there was a loss of about 15 per cent. of free iodine. In his view it was an error to recommend such an unstable preparation as a simple alcoholic solution of iodine. He believed that the requirements of solutions of iodine are met by the two solutions at present official—tinctura iodi mitis and tinctura iodi fortis.

THE DISPENSING OF SYRUPS.

Some notes on Syrup of Senna were contributed by Mr. THOMAS MCLACHLAN. Many of the present syrups of the Pharmacopœia, he said, are liable to ferment, and it suggested that more rigid standards should be adopted i the forthcoming pharmacopœia, both as regards manufactu and standardisation of the final product. He referred to the practice of dispensers of rinsing bottles under the tap immediately before dispensing; the result is that water left in the bottles when these are emptied carelessly. Som syrups and elixirs are prepared carefully with an extremel narrow margin between the amount of sugar necessary prevent either crystallisation or fermentation, and it therefore necessary that such syrups should be dispensed dry bottles.

CAFFEINE AND THEOPHYLLINE.

Messrs. P. A. W. SELF and W. R. RANKIN (laboratorie Messrs. Harrison and Self) quoted experiments wh illustrated suitable conditions, and the degree accuracy obtainable, in the preparation of caff from theobromine and theophylline by methylation w dimethyl sulphate. It has long been known that caffe can be prepared readily from theobromine, but no sim method has hitherto been published by which theobrom can be converted into caffeine with sufficient care a accuracy to serve as a method for the determinatio theobromine.

Mr. G. W. FERREY (laboratories of James Woolley, Sc and Co.) contributed a paper on the Theophylline Sodi Acetate of Commerce. One of his objects was to point the need for careful examination of parcels coming for as theophylline sodium acetate, as substitution of t article by the isomeric compound theobromine sodium acet appears to be fairly frequent. One of the consequences such substitution is that the use of theobromine as theoph line would lead to unexpected clinical results, depriving th patient of the proper treatment.

TESTS FOR MERCUROCHROME.

Mr. H. A. MITCHELL (laboratories of Evans' Biologic Institute) read a paper on the Correlation of Chemical and Toxicity Tests on Mercurochrome. The standardisation of mercurochrome involves not only a determination of it germicidal power, but, what is more important, of its toxicity. Wide variations in toxicity occur, and the author's observations lead to the hope that at a later date more uniform batches of pure mercurochrome may become available.

ESTIMATION OF MOISTURE BY DISTILLATION.

Mr. G. MIDDLETON (laboratories of the British Drug Houses Ltd.) contributed a paper on the Estimation of Moisture by Distillation. An apparatus is described in the paper and a figure, drawn to scale, demonstrates its applicability whereby the true moisture contents of drugs can be determined with a greater degree of accuracy than by the drying method.

Mr. T. TUSTINE COCKING, from the same laboratories, read a paper on the Assay of the Official Balsams, and described a new method.

Other Communications.

Mr. F. J. TODD (laboratories of Messrs. Heynes Matthew Ltd., Cape Town) made suggestions for improvements in the present official monograph on solution of bismuth and ammonium citrate with reference to the method of preparation. The same author contributed some notes on mercuric nitrate ointment and *Liquor Eastonii.* He explained a method for the preparation of the ointment, which produces a substance with keeping properties superior to those of the official ointment.—Messrs. NORMAN GLASS and A. I. JONES (laboratories of Messrs. Evans Sons Lescher and Webb) contributed a paper embodying work carried out with the primary intention of selecting acids suitable for use in the manufacture of Lysol.—Messrs. L. A. HADDOCK and NORMAN EVERS (laboratories of Messrs. Allen and Hanburys) recommended a method for the determination of strychnine in Easton's Syrup.—Mr. C. MORTON (Chelsea School of Pharmacy) read a paper on the Hydroxy-Acid Complexes of Iron. He expressed his indebtedness to the Senate of the University of London for a grant from the Dixon Fund.—Messrs. ALAN H. WARE and VICTOR SMITH contributed a paper on the Systematic Qualitative Analysis of Powders and Extractives.

PANEL AND CONTRACT PRACTICE

EFFECT OF DANGEROUS DRUGS RESTRICTION.

IF the Home Office withdraws a medical practitioner's authority to possess or prescribe certain drugs under the Dangerous Drugs Regulations, is he thereby prevented from giving efficient medical service to insured persons? Must his name thereupon be automatically removed from the medical list? To these interesting and possibly novel questions the Minister of Health has answered "No." The Minister accepts the findings of the inquiry committee which recently investigated a representation on this point made by the Middlesex insurance committee. In those findings the inquiry committee has carefully examined the obligations of the practitioner under the Terms of Service scheduled to the Medical Benefit Consolidated Regulations, and has come to the conclusion that the restrictions imposed on the practitioner by the Home Office need not prejudice the efficiency of the medical service to the insured.

In the case which raised the question the facts were not in dispute. A most important element in the case was the absence of any evidence that any insured person had suffered by reason of the Home Office withdrawal of the practitioner's authority under the Dangerous Drugs Regulations. The effect of the Home Office order is that the practitioner cannot possess, supply, or prescribe morphine, cocaine, ecgonine, diacetylmorphine (or heroin), or their respective salts, medicinal opium, or any extract or tincture of Indian hemp, or any preparation, admixture, extract, or other substance containing any proportion of diacetylmorphine, or containing not less than one-fifth per cent. of morphine or one-tenth per cent. of cocaine or ecgonine. The respondent practitioner argued that, as he could still lawfully prescribe weaker percentages of morphine and cocaine than those specified in the Home Office order, he could manage for all practical purposes to carry out the duties of panel practice; it was true that he could not prescribe heroin in any proportion whatever, but he contended that heroin was unnecessary and could be replaced by the diluted preparations of morphine, which he was still allowed to prescribe. The inquiry committee agreed that the inability to possess, supply, or prescribe ecgonine or heroin or their respective salts was not fatal to the panel doctor. Ecgonine, they remark, is not in practice used by doctors, and all the therapeutic purposes of heroin can be served by morphine in dilutions under one-fifth or by codeine. Similarly, they continue, extract and tincture of Indian hemp are very little used, and there are satisfactory substitutes. As to morphine and its preparations, the inquiry committee report states that the practitioner could satisfy all his ordinary medical needs by prescribing in strengths below one-fifth per cent. As to cocaine, permitted substitutes, such as novocain, would suffice. As to medicinal opium and its preparations, the respondent practitioner would be able to supply or prescribe these substances by a judicious use of the 15 preparations of opium exempted from the regulations and contained in the Third Schedule of the Dangerous Drugs (Consolidated) Regulations of 1928, and also by using the other forbidden preparations with the permitted dilution (below one-fifth per cent. of morphine). The material passages in the Terms of Service are paragraphs (8) and (10) of Article 9. Paragraph (10) ("duty to prescribe") requires the practitioner to order "such drugs . . . as are requisite for the treatment of any patient." Paragraph (8) ("duty to supply drugs and appliances"), sub-paragraph (*b*), requires him "to supply to a patient where requisite . . . drugs . . . required for immediate administration or application, or required for use before a supply can conveniently be obtained otherwise under the [Medical Benefit Consolidated] Regulations." The inquiry committee thinks (and the Minister agrees) that the Home Office withdrawal of the practitioner's authority does not prevent compliance with the foregoing terms. But there remains sub-paragraph (*a*) of paragraph (8), which requires the practitioner to "supply to the patient, where requisite, drugs which are necessarily or ordinarily administered by a practitioner in person." This provision in the Terms of Service is a much more awkward obstacle. How, for example, is the panel doctor to administer a hypodermic injection of morphine when his authority to possess, supply, or prescribe morphine in such concentration as is necessary has been withdrawn? The necessity to administer morphine in this way, say the inquiry commiteee, is rare, and, perhaps, might not occur in ordinary insurance practice oftener than five or six times a year; but it is of vital importance. The only way of circumventing this obstacle, they conclude, is for the restricted practitioner to call in the assistance of a medical colleague who is not under a similar disability. They think the restricted practitioner can give adequate treatment if he has "a satisfactory working agreement with a colleague to meet a somewhat rare emergency." They apparently do not regard such a course as more objectionable than the not uncommon arrangement for surgical operations which are adjudged to be within the ordinary general medical practitioner's competence and are, therefore, within the terms of the insurance doctor's service, but which certain individual practitioners find themselves unable or unwilling to carry out personally.

It is thus possible to state as an abstract proposition that withdrawal of authority under the Dangerous Drugs Regulations by the Home Office does not mean the automatic removal of an insurance doctor's name from the medical list by the Minister of Health. Perhaps the warning should be added that the withdrawal of authority may nevertheless be a significant element in some future case where an allegation of specific inefficiency of treatment has emerged. The restricted practitioner may then be represented as working at a disadvantage which can only be removed by skilled and judicious use of permitted drugs to supplement the restricted resources. In the recent case under discussion the practitioner was in a strong position; as there was no evidence that any of his patients had suffered by reason of the restrictions, it was difficult for the tribunal to find that the medical service was inefficient.

EXCESSIVE SICKNESS CLAIMS.

Dr. G. H. CRISP (Oakham, Rutland) writes: "In your issue of July 18th there are two interesting statements. On p. 153 is the now hackneyed diatribe against the panel practitioner by Mr. S. Comyns Carr, K.C., on the issue of alleged fraudulent certificates. On p. 144 is a short account of one of the discussions at the joint conference of the British Hospitals Association and the Incorporated Association of Hospital Officers, at Eastbourne, in which it is stated that the number of patients attending the London teaching hospitals has risen by 10 per cent., and the individual attendances by 30 per cent., since 1920. As we are assured by the approved societies that there has been no increase in sickness, we must conclude that the hospitals also are participants in the alleged fraud. It is difficult to see that they derive any benefit from their lamentable conduct."

CORRESPONDENCE

PRIORITY IN NEUROLOGICAL SURGERY.

To the Editor of THE LANCET.

SIR,—May I, as one of Victor Horsley's former pupils and colleagues, do a tardy justice to his acknowledged greatness both as a neurologist and a surgeon, by pointing out in your columns the inaccuracy of the oft-repeated claim in American publications that Spiller of Philadelphia, in 1898, was the *first* to suggest section of the sensory root of the fifth nerve for the relief of trigeminal neuralgia?

I am the more prompted to do so by the appearance in the *Journal of the American Medical Association* (March 21st, 1931) of the latest article of many by Dr. Charles Frazier, in which he continues to advance this claim, and further states: "The first purposeful section of the sensory root for the relief of trigeminal neuralgia was performed in this clinic." Neither of these claims can be substantiated. For it was Victor Horsley who first suggested the procedure and who first carried it out, exactly eight years prior to the appearance of Spiller's suggestion contained in his paper, written in collaboration with W. W. Keen, in the *American Journal of Medical Sciences*, for November, 1898.

In the *British Medical Journal*, of Dec. 12th, 1891 (p. 1249), in the last of three consecutive articles written in collaboration with Dr. James Taylor and Dr. W. S. Colman, Horsley says:

> "In considering the possibility of relieving cases of inveterate neuralgia, when recurrence of pain had taken place—i.e., after peripheral operations, I thought that one might be able to remove the Gasserian ganglion, *or divide the fifth nerve behind it* (italics mine), and I made, some years ago, dissections to see how far the Gasserian ganglion could be separated from the cavernous sinus. Finding this to be the case (that complete removal of the Gasserian ganglion is not possible) I then considered the possibility *of dividing the fifth nerve behind the ganglion* (italics mine). On trying this on the dead body, I found that it was perfectly feasible."

Horsley then proceeds to describe very fully the various steps of the operation, done on Dec. 11th, 1890, which he deliberately undertook and performed for attacking the sensory root behind the ganglion. Further, in the *Clinical Journal*, of Nov. 3rd, 1897, he refers again to this case and says:

> "In 1890, after consideration of the whole question in a very severe case, I determined to divide the nerve roots behind the ganglion. To attain this object (post-ganglionic section) I endeavoured to raise the temporo-sphenoidal lobe, and succeeded without much trouble in detaching the sensory root from the pons."

I am sure that it will need only this letter to secure from our American confrères their ready and generous acknowledgment of Horsley's priority in both suggesting and carrying out the operation of section of the sensory root for the relief of trigeminal neuralgia.

I am, Sir, yours faithfully,

Harley-street, W., July 15th, 1931. DONALD ARMOUR.

ACUTE ASEPTIC MENINGITIS.

To the Editor of THE LANCET.

SIR,—I was greatly interested in the paper by Dr. John Gibbens in your issue of July 4th, for at the end of last year I saw what must have been a case of acute aseptic meningitis, and had remained in doubt as to the diagnosis.

The patient, a boy aged 6, was taken acutely ill on the night of Oct. 27th with abdominal pain, fever, vomiting, and headache. The onset was so sharp, and the abdominal symptoms so predominant, that it [illegible] considered wisest to explore the abdomen, and [illegible] somewhat congested and œdematous appendix [illegible] removed. However, the symptoms persisted, and I [illegible] asked to see the child on Oct. 31st. By that time the signs of meningeal irritation were well marked; the child was irritable, lying curled up, with head slightly retracted, rigid neck, and periodic vomiting. Otherwise there were no abnormal signs.

The cerebro-spinal fluid was under only moderate pressure. Dr. Eric Wordley reported on it as follows:—

> "A turbid fluid, containing obvious pus. No clot present. Cells numbered 80 per c.mm.; 95 per cent. polymorphs; 5 per cent. lymphocytes; protein, 60 mg. per cent.; chlorides, 71 mg. per cent. No organisms were found in the stained films and cultures were sterile."

The boy seemed better as a result of the lumbar puncture, and this was repeated four days later, the cerebro-spinal fluid showing no change.

For two weeks the case ran an extraordinarily variable and irregular course. On some days the temperature would rise to 102°, and headache, vomiting, and general irritability recur with severity; on other days the fever would be slight, only reaching 99°, and the boy would sit up and play with his toys and talk perfectly rationally. His general condition remained remarkably good throughout.

On Oct. 11th there was complaint of a little tenderness over the left mastoid, with slight enlargement of the left pupil and weakness of the left face; but no other evidence pointing to disease of the ears was found. On that day I gave an injection of 1 c.cm. sodium nucleinate solution, and after a slight reaction the temperature fell to normal and the pulse-rate to 88, and remained at these levels for two days. Then headache and vomiting recurred, and the temperature rose to 102°. I repeated the nuclein, therefore, 0·5 c.cm. daily for a week, and at once the temperature and pulse returned to normal, and the child made an uninterrupted recovery. A lumbar puncture on Nov. 24th gave a clear cerebro-spinal fluid containing a slight excess of protein, and a definite excess of cells (total count not done), 90 per cent. of which were lymphocytes.

In every way the case agrees with those described under the title "acute aseptic meningitis."

I am, Sir, yours faithfully,

Plymouth, July 17th, 1931. W. A. LISTER.

LATENT MAXILLARY SINUSITIS.

To the Editor of THE LANCET.

SIR,—Dr. R. Paterson's lucid and most instructive paper in your last issue (p. 117) wisely stresses the possibility of antral infection being totally unsuspected. During the last two years I have habitually subjected these cavities to transillumination in the course of a routine physical examination, and have notes of 11 cases in which one or both antra were opaque and in which no local symptoms whatever were present. Four of the patients suffered from chronic arthritis, two from bronchitis, two from angina pectoris, one from duodenal ulcer, one from hyperpiesia, and one from asthma. Pus was present in two arthritics and one bronchitic. The latter's chest condition cleared up as the result of antral drainage, but the former two showed no general improvement. Of the remaining cases, exploratory puncture produced no pus, but the wash-out fluid was turbid, and contained *Streptococcus viridans* in three, *Micrococcus catarrhalis* seven, and was sterile in one anginal patient. A ypoid mucous membrane was found in the cases of hma and duodenal ulcer, the other antra being eated by wash-outs only. The asthmatic showed no improvement; this is usual. The ulcer, of course, healed on the usual medical treatment, and it is doubtful whether clearance of the antrum had any general beneficial effect.

Although it is probable that many cases of latent maxillary sinusitis are no better, as regards general health, for its discovery and treatment, yet there remains a considerable fraction of unsuspected instances of this condition in which suitable treatment will result in the disappearance of diverse maladies.

In nearly every case adequate transillumination can be obtained by the use of a convenient and inexpensive electrically lighted tongue depressor in conjunction with a good dry battery (I use one supplied by F. Davidson and Co., Great Portland-street), both of which can be carried round with ease, and in fact used for the normal examination of mouth and throat.

I am, Sir, yours faithfully,

A. H. DOUTHWAITE.

Harley-street, W., July 18th, 1931.

To the Editor of THE LANCET.

SIR,—Dr. Paterson's interesting and timely article deserves wide notice. As has rightly been emphasised, the symptomatology in these cases of unsuspected antral infection is usually that of some secondary complication. In a paper read before the Tuberculosis Association last year,[1] I emphasised the fact that cases of secondary "catarrhal" chests ("catarrhal apices," &c.), following antral infections and sepsis generally in the upper air passages, are constantly being notified as tuberculous because of symptoms such as cough, blood-stained expectoration, general malaise, loss of weight, and sweating. If the upper respiratory tract were examined as a routine procedure in every chest case, such a misfortune, no doubt, would be avoided.

The continuity of the whole of the respiratory tract should require little emphasis. Nevertheless, there is an unfortunate tendency to divorce the upper and lower respiratory tracts and treat them in isolated compartments, and the absence of team-work between rhinologists and physicians is to be deplored. Whilst the consequences of a diagnosis of the pulmonary complications of antral infections such as pulmonary tuberculosis may indeed be serious for the patient, we must furthermore recognise that failure to detect latent maxillary sinusitis is responsible for the development of many cases of bronchiectasis and other serious pulmonary complications, the lungs serving as "cesspools" for upper respiratory tract discharges. There is, therefore, urgent need for: (1) More serious team-work by physicians and rhinologists in order that the more distant symptoms of a focal infection shall be recognised. (2) The recognition of an elementary principle—that no examination of the chest is complete unless it includes an examination of the upper air passages, and that in both branches the fullest use of clinical and radiological methods should be employed.

Whilst I have limited my remarks on latent antral infection to its pulmonary complications, its significance in almost every branch of medicine has been illustrated in Dr. Paterson's admirable paper.

I am, Sir, yours faithfully,

Harley-street, W., July 20th, 1931. PHILIP ELLMAN.

A CASE OF IODISM?

To the Editor of THE LANCET.

SIR,—An unusual case of what appears to be iodism came to my notice last week. A man, aged 42, and, a few days later, his wife, came to me complaining of a sore tongue. I was at a loss at first to account for this, as there were no signs of dyspepsia or history of excessive smoking in either case, and the usual remedies gave very little relief.

On her second visit, the wife mentioned the hitherto forgotten symptom, common to both herself and her husband, of a metallic taste in the mouth. I knew they were taking no medicine containing iodine or iodide, and at first could not account for this. On inquiry as to the salt used in the household I was told that for the last 12 months "iodised" salt had been used.

Can the cumulative effect of an unknown dose of iodine or iodide used in the preparation of this commodity have caused the taste in the mouth and the sore tongue in these cases? Also, could it account for some of the cases of acne one treats with very little knowledge as to cause, and lack of response to treatment?

I should be glad to know of any other cases similar to my own.

I am, Sir, yours faithfully,

KATHLEEN BLAKE, M.R.C.S., L.R.C.P.

West Wickham, Kent, July 15th, 1931.

INSULIN PHOSPHOTUNGSTATE BY MOUTH.

To the Editor of THE LANCET.

SIR,—In your issue of Jan. 24th (p. 184) Dr. R. D. Lawrence reported clinical results with oral administration of insulin phosphotungstate as proposed by H. N. Mukhirjee.[1] Having tried the preparation on two cases, Dr. Lawrence failed to observe any lowering of the blood-sugar. About the same time Dr. E. G. B. Calvert tested the substance on a case at the London Temperance Hospital, and the results we obtained were in agreement with those of Dr. Lawrence. The tests were carried out as follows:—

Having first found by a blood-sugar curve the effect of 25 g. of glucose administered to the diabetic patient fasting, a few days later the same patient fasting was given 25 g. glucose and 100 units of insulin phosphotungstate orally, and the sugar curve was again plotted out. A week later the sugar curve was obtained after substituting 25 units of insulin hypodermically for the insulin phosphotungstate, while a fourth curve was obtained after the patient had taken 600 units of insulin phosphotungstate by the mouth. The following are the figures obtained, the same patient being tested and 25 g. of glucose being taken, fasting, on each occasion.

	1	2	3		4
—	Without insulin.	100 units insulin phosphotungstate orally.	25 units insulin hypodermically.	—	600 units insulin phosphotungstate orally.
Fasting ..	0·218	0·252	0·218	Fasting ..	0·252
½ hour ..	0·296	0·282	0·228	½ hour ..	0·301
1 hour ..	0·38	0·34	0·247	1 hour ..	0·36
1½ hours ..	0·365	0·345	0·252	1½ hours ..	0·394
2½ hours ..	0·355	0·267	0·169	2 hours ..	0·336
3½ hours ..	0·326	0·267(?)	0·081	3 hours ..	0·291
4½ hours ..	0·267	0·242	0·11	4 hours .	0·272

The insulin phosphotungstate was prepared by Messrs. Allen and Hanburys, Ltd.

As the subject is of considerable importance, I am, with the concurrence of Dr. Calvert, sending you these results of our investigations.

I am, Sir, yours faithfully,
HAROLD H. SANGUINETTI.

Hornton-street, W., July 20th, 1931.

RECTAL HÆMORRHAGE IN UNSUSPECTED TYPHOID.

To the Editor of THE LANCET.

SIR,—I have just read with great interest Mr. Hamilton Bailey's note in your issue of June 13th on three cases of Alarming Rectal Hæmorrhage in Unsuspected Typhoid, to which I should like to add my own recent case, referred by Dr. F. R. S. Shaw, of Tuz Khurmatu, which on arrival from up-country had passed the alarming stage, and presented a problem for diagnosis. I cannot do better than quote Dr. Shaw's note of Dec. 16th, 1930:—

> Yesterday afternoon Mr. A. was feeling a little faint while working and was suffering from a good deal of flatulence, but was otherwise all right. Later in the evening, he felt rather full in the stomach and still suffered from flatulence. He vomited twice and had three motions. He describes the vomit as coming up easily without any straining or pain, and says it was dark coloured. About 2.30 A.M. I was called out and found him lying in bed in a collapsed condition, cold, very pallid, with a feeble rapid pulse, just like a person who has had a severe hæmorrhage. The history he gives me is as follows: About half an hour previously he had been out to the latrine, had vomited a little and had had a motion much the same as in the afternoon. On returning to the bathroom, he started to pass a very large watery motion without having any control over it. To avoid soiling any place, he sat on the edge of the tin bath and just let everything pass. He then collapsed, but managed to call the person next door, who roused me. There was some water in the bath, so that it was very difficult to see what the motion was like. However, he soiled his pyjamas badly, and it looks to me to be a black pasty material, something like iodex, but blacker. The other noticeable thing was its lack of odour. He gives a history of chronic flatulence, but of nothing else. I can see no reason for the colour of his motion unless it is blood. This morning his temperature is 99° and pulse 100 and feeble. Tongue dirty, and he is very thirsty. On palpation his abdomen shows nothing, but a certain fullness and possibly a little increased rigidity over McBurney's point, but that is rather indefinite. I have done a rough test with tincture of guaiacum and ozonic ether on the stained pyjamas and get a positive reaction for blood.

On admission at 6 P.M. on Dec. 16th the temperature was 99° F., the pulse-rate 76, and the general condition as described by Dr. Shaw. On Dec. 17th, and for ten days thereafter, he passed many liquid stools containing altered blood with very small clots, and once a little recent blood. The Widal reaction on Dec. 17th was positive to *Bacillus typhosus*, *paratyphosus* A, and *paratyphosus* B 1/20–1/40 and negative to all three in 1/80–1/640. As the patient had been inoculated with T.A.B. four months previously this result could not be regarded as other then residual. The Wassermann reaction was completely negative. On Dec. 28th a further Widal showed *B. typhosus* positive 1/20–1/320, neg. 1/640, *paratyphosus* A and *paratyphosus* B remaining as on Dec. 17th, 1930. This result clinched the diagnosis. The patient did well and was discharged on Jan. 13th, 1931.

The Widal reaction is rarely a dependable clinical aid before the end of the second week. With regard to Mr. Bailey's mention of bilharzia—although lower Iraq shows a very large incidence of the urinary type of this disease, I have not seen more than half a dozen cases of the rectal form in 14 years, and in none of these was there a severe rect hæmorrhage. However, workers in Egypt where I understand, rectal bilharzia is fairly common will, I am sure, be able to make an authoritati statement on this point.

I am, Sir, yours faithfully,
G. S. WOODMAN, F.R.C.S. Edin.

The Royal Hospital, Bagdad, Iraq, July 8th, 1931.

RECOVERY FROM STREPTOCOCCAL SEPTICÆMIA.

To the Editor of THE LANCET.

SIR,—Dr. J. A. Ryle's letter requires some comment.

(1) The recovery-rate of 6 cases out of 21 from the Guy's Hospital report was quoted because these appeared to be an unselected series of cases admitted to hospital, and because, as stated by Drs. Ryle and Smith in the report, they served "once more to remind us of the gravity of streptococcal blood-poisoning." Obviously, neither the cases which occurred in the hospital, nor those from private practice (which I do not agree are a parallel series), have statistical value, since (*a*) in some of the cases the clinical diagnosis was not supported by bacteriological evidence; (*b*) in other cases it is simply stated that streptococci were found—whether or not they were hæmolytic streptococci is not mentioned; (*c*) in no case was the hæmolytic streptococcus, when found, typed; (*d*) in some of the cases there was a septic focus which could be, and was, treated surgically, while in others this was not the case; (*e*) the nature of the treatment varied.

(2) Ryle and Smith state in the report "that there are four manifestations which may be regarded

---

[1] Jour. Physiol., 1930, lxx., 182. See THE LANCET, 1930, ii., 707.

as peculiarly diagnostic of streptococcal fever and as expressing, we believe, infection with a hæmolytic strain."

In view of the facts mentioned above, I am not prepared to agree that sufficient evidence has been produced that any such "diagnostic syndrome" exists for streptococcal septicæmia. Many cases of hæmolytic streptococcal septicæmia occur without one or other of the symptoms mentioned and some without any; in my opinion, any insistence on *certain clinical* features of the condition militates against the application of what is undoubtedly the most important proceeding—viz., a complete bacteriological examination of the case. How frequently *does* one hear it said, "It cannot be septicæmia," because the patient has not a certain symptom.

(3) With regard to serum treatment, the article by Ryle and Smith states that "there seems very little evidence in favour of the efficacy of serum therapy," and a considerable warning is given with regard to serum sickness, with reference to a severe and crippling case of this condition. It is not stated, however, how this case was treated with serum, nor whether the serum was concentrated or unconcentrated.

I am in entire agreement with Dr. Ryle as to the disappointing results which occur so frequently with serum therapy in cases of streptococcal septicæmia, and also that it is highly probable that the use of other types of sera was a factor in the recovery of the case which we described. I am personally quite satisfied that the change in the serum used was the determining factor in the recovery of the patient, since improvement was immediate after this, although, of course, as with every other therapeutic agent which is used, the difficulty of distinguishing between *post* and *propter* effects exists. I see many cases of diphtheria which *might* recover without the use of antidiphtheritic serum; on the other hand, they *might* die. The important thing is to investigate why, in a limited number of cases of septicæmia, serum does appear to have a specific effect, while in others it has none.

I do not agree with Dr. Ryle that a careful study of the natural history and course and variable mortality of streptococcal septicæmia will yield an advance of our knowledge of serum therapy, unless with this is combined a most exhaustive study of the various types of hæmolytic streptococci, and further investigation as to the possibility of more specific antitoxic sera for the different types than we have at the present time.

I am, Sir, yours faithfully,

A. H. G. BURTON.

Health Offices, Ilford, July 21st, 1931.

BACTERIOLOGICAL CONTROL OF MILK-SUPPLIES.

To the Editor of THE LANCET.

SIR,—Whilst the findings of Prof. McIntosh and Dr. Whitby, recorded last week in THE LANCET, are of considerable importance, it is sincerely to be hoped that they will not be the cause of any precipitate, and possibly quite unwarranted, action on the part of public authorities. In the absence of either experimental or epidemiological evidence that the two organisms mentioned have any sanitary significance, it would be advisable to defer reconsideration of the question of standard nutrient medium until the matter has been investigated further, preferably in coöperation with the large dairy companies. When the lemco-peptone-agar medium was *first recommended* by the American Public Health Association, the Milk Control Committee, of which I was a member, well recognised that this medium did *not give the total* number of organisms present, but we considered that this disadvantage was more than offset by certain advantages only to be *obtained by* the use of ingredients of comparatively constant composition (lemco and peptone).

The main desideratum as regards the control of milk counts is that the standard process shall be capable of giving approximately the same result when used by different workers; if this condition is not fulfilled, chaos and confusion will result; and other considerations must be subordinated to this until a superior nutrient medium is evolved.

The experience recorded by Prof. McIntosh and Dr. Whitby reminds me of a somewhat similar one which I encountered in Toronto during the winter of 1911–12. In addition to the standard media of the American Public Health Association, I was using a gelatin medium for making counts on the water filter effluents and during a very cold spell, when the lake was partially covered with ice, I was alarmed to find that the bacteria per c.cm. had suddenly increased from 15–20 up to several thousands, although the agar count at blood-heat and the *B. coli* content remained quite normal. Investigation showed the anomaly to be due to a psychrophilic, non-pathogenic micrococcus that was, fortunately, very susceptible to chlorine treatment, which formed the second line of defence in the system of water purification.

I am, Sir, yours faithfully,

Buxton, Derbyshire, July 21st, 1931. JOSEPH RACE.

TUBERCULOUS BACILLÆMIA.

To the Editor of THE LANCET.

SIR,—In the annotation on this subject on p. 140 of your last issue you express the opinion that it is highly desirable that Prof. Loewenstein's work should be repeated in this country. Your readers will be interested to learn that Dr. H. Moos Schwabacher has made further progress with the investigations reported in THE LANCET of May 23rd, and that she has now obtained tubercle bacilli in pure culture in three cases, using a modification of Loewenstein's original technique—I am, Sir, yours faithfully,

KENNETH ECKENSTEIN,
Hon. Pathologist to the French Hospital.

Shaftesbury-avenue, W.C.2, July 20th, 1931.

OPENING OF KING GEORGE HOSPITAL, ILFORD.—On Saturday last the King, who was accompanied by the Queen, opened the new hospital named after him at Ilford. Their Majesties also visited the Dagenham Health Centre of the hospital.

CITY MATERNITY HOSPITAL.—A committee has been appointed by the governors of St. Bartholomew's Hospital to consider a proposal for the amalgamation of the London Maternity Hospital, City-road, which was founded in 1750. The proposal is to erect an entirely new hospital either on the St. Bartholomew's estate or on an adjoining site. It is stated that the scheme would entail a capital outlay of approximately £120,000 with a maintenance cost of about £30,000 per annum. The 71 beds in the City-road Hospital are stated to be *totally* inadequate, and the suggested building would provide 130. Moreover, the noise of traffic is troublesome to the patients. St. Bartholomew's is in urgent need of a maternity hospital close by *for teaching purposes—it has only* 17 maternity beds. The site of the City-road Hospital is the property of St. Bartholomew's, and it is thought that it could be sold for about £50,000; the maternity hospital also has available money.

PUBLIC HEALTH SERVICES

LOCAL AUTHORITIES AND ADVICE ON BIRTH CONTROL.

LAST March the Minister of Health issued a Memorandum[1] on the use of local authorities' institutions for advice on methods of birth control. He finds that certain misconceptions have arisen about the views there expressed, and the Ministry has accordingly sent a supplementary circular to maternity and child welfare authorities, bringing the following points to their notice.

It is necessary, the Minister believes, to emphasise the statement in the Memorandum that the Government are advised that local authorities have no general power to establish birth control clinics as such. Under the Maternity and Child Welfare Act, 1918, their powers are limited, so far as women are concerned, to making arrangements for attending to the health of expectant mothers and nursing mothers. If an authority decides to provide facilities for giving birth control advice at a maternity and child welfare centre the use of these facilities must be strictly incidental to the purpose for which the centre is established, and they can be made available only for married women who are either expectant or nursing mothers already in attendance at the centre and whose cases further pregnancy would be detrimental to health.

If action is taken under the Public Health Acts to establish a clinic at which medical advice and treatment would be available for women suffering from gynæcological conditions, the use of any facilities provided at the clinic for giving advice on contraceptive methods must be strictly incidental to the purpose for which the clinic is established—viz., the treatment of sick persons. Only women who need medical advice and treatment for gynæcological conditions can properly be admitted to the clinic, and contraceptive advice can properly be given only to married women in attendance at the clinic in whose cases pregnancy would be detrimental to health. It is obviously desirable for a local authority to obtain the services of a medical officer specially experienced in the clinical advice and treatment needed at a gynæcological centre of this sort.

The Minister does not consider it desirable that a gynæcological clinic should be established at a maternity and child welfare centre, and if an authority is satisfied that there is need for such a clinic it should be provided in separate premises or at a hospital. Expectant mothers and nursing mothers in attendance at maternity and child welfare centres who are found to need medical advice and treatment for gynæcological conditions could then be referred to the clinic. He thinks it important that no existing officer of a local authority should be prejudiced in any way by a decision of the authority to provide facilities for birth control advice within the limits laid down in the Memorandum. This work should not be regarded as falling within the scope of the normal duties of the medical officers of a local authority, and they should be free to undertake it or decline it.

SCHOOL MEDICAL SERVICE.

—	No. on roll.	Average attendance.	Routine inspections.	Special exams. and reinspections.	Percentage of defects.
County of Warwick..	—	—	10,839	8,975	23·3
County of Brecon ..	9,076	8,103	2,639	1,316	12·31

County of Warwick.

Dr. A. Hamilton Wood discusses many topics which are in the minds of all concerned with school medicine to-day.

He notes the great extension of facilities for car and treatment that have been made in his area. He believes that the variations in the number of defecti found are largely attributable to personal factors—changes in staff yield differences in standard whic cannot immediately be made uniform. Figures fo defects of vision and other conditions not readil affected by the personal factor in diagnosis hav been comparatively constant. He suggests th the high percentage of other defects in his coun may be partly explained by the increase of thro affections, due to climatic conditions or to so nutritional defects in early childhood, leading an enlargement of the lymphoid tissue of the na pharynx, which in turn is subject to inflammat when influenced by excessive or continued rainf Dr. Wood says that as a result of his appeal in last annual report for additional medical staff Kelly was appointed last year, and he records a the recent appointment of an additional whole-ti dentist and three whole-time dental nurses. percentage of acceptances of tonsillectomy dental treatment are regrettably small. The den obtained on average only 30·4 per cent. accepta compared with 58·5 for the whole country in One obstacle which may be an effective deterrent during this period of trade depression is the charge of 1*s*. It might be urged that dental treatment is really a preventive service, and thus should be given free, as is the treatment of infectious diseases; but since the Medical Treatment Act makes some charge obligatory, the experiment of lowering the sum to 6*d*. might prove instructive.

The school dentist in his report attributes the low percentage of acceptances to the fact that a general public dental service in Warwickshire is only of recent origin; the parents are so ignorant of modern conservative methods that they have a general distrust of fillings, which they seem to view as the first step towards the destruction of a tooth. Attempts to interest parents have been unsuccessful, and since it is realised that they often follow the wishes of the children, attention has been concentrated on lectures in the schools. Head teachers have done much, and can do still more, in influencing children and parents to accept treatment. As to tonsillectomy, the reasons for a percentage of acceptances as low as 50 are thought to be: (1) that the parents discredit the advice of the medical officers; against such a view must be put the fact that the number of parents attending the medical inspections in the county is steadily increasing; (2) the charge of 5*s*.; (3) the inconvenience of taking the child to hospital; (4) the occasional discomfort and disturbing after-effects. This last factor could be diminished if all hospitals admitted patients for at least 48 hours.

County of Brecon.

The area with which Dr. H. Davies has to deal contains for a whole county a relatively small school population, and there are lacking many of the facilities found in some progressive centres of population. The authority has no special schools of any kind of its own, no nursery schools, no X ray installation for the treatment of ringworm, no organisers of physical training, and no coöperation of voluntary societies except the N.S.P.C.C. Since all such valuable agencies are lacking, and since Dr. Davies, who is medical officer of health for the county with only one assistant, has to carry out all his duties over a widely-scattered area, it would not be surprising if the ascertainment of defects were not so strict as in some other places. The fact that the percentage of children found to have defects is only 12·31 compared with 20·7 for England and Wales (in 1928), and that only three cases of otitis and defective hearing were noted, may be due not so much to the superior health in Brecon as to the exigencies of the school medical service.

---

[1] See THE LANCET, 1931, i., 776.

On the subject of malnutrition, it is recorded that the committee is concerned about the physical welfare of the children. Milk is being supplied to ill-nourished children in many of the schools, and frequently cocoa also, at a cheap rate. Many of the school buildings are defective, some of them so unsatisfactory that, in the opinion of Dr. Davies, proper conditions of light, warmth, and fresh air could be obtained more cheaply by erecting new ones than by adaptation. In other places, however, quite small alterations provide marked improvements. Repainting walls in a clean light colour instead of the dark buff may not only make a room more cheerful but raise the reflective power of the walls by over 40 per cent. Cleaning has been made much easier by the removal of heavy desks and furniture and by other simple devices. He fears, however, that the benefits derived from improved school buildings are being negatived by bad housing conditions.

County of Rutland.

r. Christopher Rolleston, who is responsible for land as well as the Soke of Peterborough, is spoken in his condemnation of some of the conditions he has to cope with. He says that there is hardly a single school in the county which comes up to modern requirements, and that grossly insanitary conditions still exist in the shape of privy vaults in certain schools. The water supply also is quite inadequate, but Dr. Rolleston considers that the question of water supply to schools must wait upon a general scheme for the whole county, or even possibly for the whole of rural England. He cites many improvements made during the past few years. The new central schools are temporary buildings—"old army huts, but they seem to answer their purpose, and they have the advantage of not lasting for centuries. The hygienic ideas of one generation become the abomination of desolation of the next." He draws a striking picture of the development of the school medical service from 1910, when there was no school nurse, to the present time. The arrangements for treatment have progressed gradually during this period. During the year the committee continued the policy of asking for small payments for the various forms of treatment (other than X ray treatment) from the few parents whose means are within the prescribed income limit.

The provision for dentistry has been inadequate, but it should be possible to complete the round of the school in a year now that the working time of the dentist has been increased. The advice received from a dental expert attached to the Board of Education was that dental attendants should invariably be provided, though it was considered unnecessary that the attendant should be a trained nurse. The essential qualities were said to be adaptability, neatness, method, intelligence, and some knowledge of clerical routine. Dr. Rolleston's comment is that such paragons are not easily to be found. He adds that the committee "provided the school dentist with help which proved nothing more than an encumbrance."

The percentage of parents present at the examination of their children was over 80, which may be regarded as a tribute to the personality of the medical officer. Dr. Rolleston makes some observations on the teaching of hygiene in the schools; on the whole he is satisfied with the effort made, but considers that hygienic teaching can scarcely be said to occupy any definite place in the course of instruction. He praises the valuable instructions given by the busy school nurse, and proposes to supplement the teaching by individual talks to each child examined.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 11TH, 1931.

Notifications.—The following cases of infectious disease were notified during the week: Small-pox 45 (last week 56); scarlet fever, 1378; diphtheria, 892; enteric fever, 61; pneumonia, 618; puerperal fever, 39; puerperal pyrexia, 105; cerebro-spinal fever, 44; acute poliomyelitis, 6; encephalitis lethargica, 10; dysentery, 27; and ophthalmia neonatorum, 112. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on July 14th–15th was as follows: Small-pox, 64 under treatment, 1 under observation (last week 97 and 1 respectively); scarlet fever, 1125; diphtheria, 1471; enteric fever, 18; measles, 143; whooping-cough, 448; puerperal fever, 39 (plus 12 babies); encephalitis lethargica, 206; poliomyelitis, 2; "other diseases," 133. At St. Margaret's Hospital there were 12 babies (plus 3 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there were no deaths from small-pox, 2 (1) from enteric fever, 18 (0) from measles, 6 (1) from scarlet fever, 17 (3) from whooping-cough, 20 (2) from diphtheria, 35 (8) from diarrhœa and enteritis under two years, and 20 (3) from influenza. The figures in parentheses are those for London itself.

Three deaths from meningococcal meningitis were registered in London, one in an infant and the others in age groups from 25 to 45. There were two deaths from measles in Liverpool, Leeds, and Sunderland. Four fatal cases of diphtheria were reported from Leeds, three from Birmingham, and two each from Manchester and Salford. Diarrhœa and enteritis under two years caused three deaths in Sunderland, and two each in Stoke-on-Trent, Birmingham, Leeds, Sheffield, and Hull. Four deaths from influenza occurred in Birmingham.

The number of stillbirths notified during the week was 285 (corresponding to a rate of 41 per 1000 births), including 43 in London.

ANTS IN A HOSPITAL.—At a meeting of the Glasgow corporation recently complaints were made that there is a visitation of ants at Shieldhall fever hospital. It was stated that children's cots had been invaded, and the food in patients' lockers speedily became infested. The convenor of the public health committee explained that steps are being taken to deal with the ants, and that the creatures were harmless and "did not attack the patients."

EXTENSION OF ASHINGTON HOSPITAL.—On behalf of the Central Miners' Joint Welfare Committee, which made a grant of £10,000 towards the cost—£15,000—extensions of this hospital have been formally handed over. The enlargements comprise a new orthopædic department, an improved out-patients' department, a new theatre, and various accessories. During 1930 over 1000 patients were admitted, there were 22,000 out-patients, and more than 14,000 orthopædic cases were dealt with.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS.

HOUSING IN RURAL AREAS.

THE House of Commons on July 16th considered the Housing (Rural Authorities) Bill on Report. On July 17th the third reading of the Bill was agreed to without a division.

BETHLEM HOSPITAL BILL.

On July 17th, in the House of Commons, Mr. Lansbury, First Commissioner of Works, moved the second reading of the Bethlem Hospital (Amendment) Bill, which has already passed through the House of Lords.

Mr. A. M. Samuel said he welcomed the Bill and the opposition would be glad to do all they could to facilitate its passing into law. It was due to a gracious and generous action and one that the House would approve.

Mr. Strauss said he could not help expressing regret that it had been found necessary to introduce the Bill to legalise the arrangement which had been come to with the donor of the park, the borough council, and the County Council. He did so because there was a very serious shortage of open spaces in that area, and those who were interested in the district were very jealous of every single acre of open space available. Under the force of necessity, almost, it had been agreed that a portion of the Bethlem Hospital site should be retained for the Imperial War Museum, but the people of Lambeth and Southwark would very much rather have an open space to play in than a war museum in their area.

Mr. Lansbury said that the Bill was going before a select committee because it was a private Bill and might affect private interests. He believed that some part of the present buildings would be destroyed. The fact was that there was no proper accommodation for the museum where it was at present. In reply to Mr. Strauss, he wished to say that they wanted every inch of land they could get for the children. They must live somewhere and they must be sheltered, and if they had pulled down the building entirely they would have had to put up a shelter for them.

The Bill was read the third time and committed to a select committee of five members.

The money resolution in connexion with the Bill was afterwards agreed to in committee.

STERILISATION OF MENTAL DEFECTIVES.

On July 21st, in the House of Commons, Major Church asked leave to introduce a Bill to enable mental defectives to undergo sterilising operations or sterilising treatment upon their own application, or that of their spouses, or parents or guardians. He said that those associated with him realised that in making this request for permission to introduce this Bill they were asking the House to do something which could be regarded as being in advance of public opinion. (Hear, hear.) They realised that they had got to convert a large section of the people to a full appreciation of the principles underlying the Bill. His opinion, although it was not that of all those associated with him in promoting this measure, was that this was merely a first step. It was a step in order that the community as a whole might be able to make an experiment on a small scale, so that later on the community would have the benefit of the results of the experience gained and be able to come to conclusions before compulsory sterilisation proposals for unfit persons were put forward.

The Bill was based on the willingness of those suffering from mental deficiency to undergo voluntarily an operation which would prevent them bringing children into the world. The Bill provided every reasonable safeguard for the voluntary principle. In the first place, the patients themselves must consent to the operation, or their spouses, or parents or guardians, must agree to the operation. In the third place there must be consent on the part of the Board of Control, and finally the operation could only be carried out after approval had been given by a judicial authority, such as a bench of magistrates. The operation would not be the mutilation usually associated with sterilisation. It was devised in order that the emotional life of the person operated upon should not be affected in the slightest degree, but that the patient should be effectively prevented from bringing children into the world. On the male there would be a very simple operation, which could be easily done in five minutes with a local anæsthetic, and there was no danger attached to it. Out of 5000 cases dealt with by the State of California there was only one death, and that was under the anæsthetic. In the case of women it was a rather more serious operation, but no more dangerous than an operation for appendicitis.

The Mental Deficiency Committee set up in 1925 and whose report was published in 1929, estimated that the certifiable mentally defective persons in the country numbered 300,000, of whom 25,000 were in institutions and another 50,000 were under the control of guardians. The committee had no recommendations for dealing with the remainder, but they recommended that institutions should be provided for one third of them—i.e., for 100,000 persons. That in itself was a tremendous drain upon the public purse and would tax the capacities of the local authorities for many years to come. But even if institutions were provided for 100,000, what was to be done with the other 200,000?

The headmaster of one of the schools for mental defectives had stated that they went out into the world at the age of 16, and that within two or three years 25 per cent. of them had been before magistrates' courts or children's courts in various parts of the Metropolis. He also stated that three or four years after leaving school many of these children had married and had had children, or had had children without being married. It might be urged that mere sterilisation was not enough and was not a cure for the problem of mental disease. He and those associated with him did not suggest that it was; but they suggested that since knowledge compiled as to the ancestry of mental defectives in a number of different states and countries showed that anything from 45 to 80 per cent. of the mental defectives had inherited defective germ plasm, it would be advisable to take the risk of sterilising the defectives, and that in the course of a generation or so their number could be reduced to measurable size. If the Bill was printed hon. Members would see that so far from attempting to violate the laws of morality all it proposed to do was something which large numbers of social workers, 53 of the borough councils in the country, whole masses of opinion in the medical and scientific professions, and many biologists believed to be the right course.

Dr. Morgan urged the House not to approve what he said was anti-working-class legislation. Nature had its own way of dealing with mental defectives—namely, by limiting their progeny. (Cries of "No.") They did not want nosey Parkers poking about, or to be influenced by eugenic nightmares. If what Major Church said was true what became of the great scientific doctrine of the survival of the fittest? There were two sources of mental defectives—those high up and those low down. It was well known that high-grade defectives had a high percentage of fertility. The cause of low-grade defectives was living under subnormal conditions nd being submerged in poverty. There were defective erm plasms in every family; and it was computed hat the chance of a defective paternal and maternal lasm uniting was one in five millions. The House hould reject this Bill and leave these poor people to e dealt with by the alternative method of segregation nd socialisation.

The motion for leave to introduce the Bill was jected by 167 votes to 89—majority 78.

HOUSE OF COMMONS.

WEDNESDAY, JULY 15TH.

Education of Mentally Defective Children.

Major **CHURCH** asked the President of the Board of ducation the total number of children under instruction schools for the mentally defective; whether any of these hools were non-provided; what proportion of the local ucation authorities provided special schools for mentally fective children; up to what age the attendance of the ildren admitted to such schools was compulsory; if atistics were available distinguishing between retarded ildren and children afflicted with known mental diseases; d if information was available with regard to the after-reers of those who had attended schools for the mentally fective.—Mr. **LEES-SMITH** replied: On 31st March, 1930, re were 15,500 children under instruction in special hools for the mentally defective. Nine of these schools e non-provided. Twenty-seven per cent. of the local thorities in England and Wales provide such special hools. Attendance is compulsory up to the age of 16. atistics are available showing the numbers of children tified as suitable for education in special schools for the ntally defective. These are children who suffer from a vere degree of retardation, or incomplete development the mind. There are no separate statistics in regard to ildren suffering from "known mental diseases," unless vere retardation itself is so regarded, but they are very few number and usually fall outside the scope of the educational stem. Records of after-careers are kept as far as possible the local education authorities and voluntary bodies ich maintain special schools.

Reception Hospitals for Mental Patients.

SORENSON asked the Minister of Health the number of on hospitals that now existed and that had been during the last 12 months in connexion with public al hospitals, and the total number of beds available in h cases.—Mr. **GREENWOOD** replied: Admission hospitals ve been provided or are under construction at about a arter of the public mental hospitals. Complete statistics n the other points raised in the question are not at present ailable, but I will make inquiry and communicate further ith my hon. friend.

New Serum for Puerperal Fever.

Mr. **RAMSBOTHAM** asked the Minister of Health if his attention had been called to the value of a new serum for preventing puerperal fever in the case of confinements; whether he intended to appoint a commission of inquiry; and whether any tests in this antitoxin had been made in the public institutions in this country and, if so, with what results.—Mr. **GREENWOOD** replied: I understand that the serum to which the hon. Member presumably refers has been and is being used for the treatment of patients in this country, but it is not yet possible to arrive at any definite conclusions as to its value. A considerable amount of research into the causes and treatment of puerperal fever is being undertaken, and is being carefully watched and assisted by the Medical Research Council and by my department. I do not consider, therefore, that there is any necessity for the appointment of a special commission of inquiry into this subject.

A Treatment for Tuberculosis.

Mr. **SMITHERS** asked the Minister of Health whether his attention had been directed to a treatment for tuberculosis called umckaloabo; and whether his department had examined it, and with what results.—Mr. **GREENWOOD** replied: The answer to the first part of the question is in the affirmative and to the second part in the negative. I am advised that the claims made in regard to this alleged form of treatment for tuberculosis do not appear to differ in character or degree from those made for many other so-called "remedies" which have been advertised from time to time and afterwards found to be valueless. I do not consider that there is sufficient ground for instituting a clinical investigation into its value.

Mr. **SMITHERS**: In view of the extraordinary success that is claimed for this treatment will not the right hon. gentleman at least ask his medical officer to look into it and report upon it?

Mr. **GREENWOOD**: Information in my department goes to show that the claim made cannot be sustained.

Lead Poisoning.

Mr. **GRAHAM WHITE** asked the Home Secretary the number of cases of lead poisoning notified during 1930 under the regulations of the Lead Paint Act and the number of cases which terminated fatally.—Mr. **CLYNES** replied: The number of cases notified during 1930 was 66. Thirteen of these cases terminated fatally.

Mr. **WHITE**: Is the right hon. gentleman satisfied that these regulations are working satisfactorily?

Mr. **CLYNES**: I have no reason to doubt that on the whole they are, but I shall be glad to receive information of particular instances where they are not.

MONDAY, JULY 20TH.

Mentally Defective Children.

Mr. **GORDON MACDONALD** asked the Minister of Health the number of mentally defective children in certified institutions in England and Wales at the latest date for which the information was available, and for each of the five years ended March 31st, 1931, giving separate figures for Lancashire.—Miss **SUSAN LAWRENCE** replied: The following are the figures asked for. The total number of mental defectives in certified institutions in Lancashire and in England and Wales respectively during the last five years was as follows:—

On Jan. 1st.	In Lancashire	In England and Wales.
1926	3,581	12,766
1927	3,627	13,342
1928	3,712	14,099
1929	3,770	14,810
1930	3,858	15,664
1931	3,919	17,200

It is regretted that separate statistics for children are not available, but it is estimated that of the total numbers given above approximately 15 per cent. are children under 16 years of age.

TUESDAY, JULY 21ST.

O.T.C. Camps and Cerebro-spinal Meningitis.

Miss **PICTON-TURBERVILL** asked the Secretary of State for War whether the annual camps of the Junior Division of the Officers' Training Corps were being cancelled this year, and if so, for what reason.—Mr. **T. SHAW** replied: Owing to the continued incidence of cerebro-spinal meningitis throughout the country it is considered inadvisable to collect boys of a susceptible age in camps in large numbers. Boys who would have attended camp but for the cancellation will, for purposes of "efficiency," be deemed to have attended.

Meningitis in the Army.

Mr. **MARJORIBANKS** asked the Secretary of State for War the number of cases of deaths from meningitis in the British Army stationed at Home during each of the last three years.—Mr. **T. SHAW** replied: The number of deaths from cerebro-spinal meningitis in the British Army at Home during the years 1928, 1929, and 1930 was 2, 9, and 10 respectively.

WOLVERHAMPTON HOSPITAL CONTRIBUTORY SCHEME.—A contributory scheme for Wolverhampton Royal Hospital is under consideration. The scheme provides for membership under the following scale: Limit of income £200 a year, or £4 a week, applicable to single persons over 16 years of age, and widows or widowers without children under 14 years of age; limit of income £250 a year, or £5 a week, applicable to married couples without children under 14 years of age, and persons with one dependant under 14 years of age; limit of income £300 a year, or £6 a week, applicable to married couples with a child or children under 14 years of age, and persons with more than one dependant under 14 years of age. The scale of contributions under the scheme is: For persons between 14 and 16, 1*d*. a week; persons between 16 and 21 and females over 21, 2*d*. a week; for others, 3*d*. a week. In the latter cases, the wife, or dependant, or children up to 14 years of age, would be eligible for hospital benefit.

OBITUARY

FRANCIS RICHARDSON CROSS, M.B.Lond., F.R.C.S.Eng., LL.D.

Mr. Richardson Cross, of Bristol, whose death on July 12th we announced last week, was held in high esteem as an ophthalmic surgeon. His practice and his reputation extended far beyond the West of England, and he was long regarded as one of the leading men of his specialty.

The son of Joseph Cross, vicar of Merriott, in Somerset, F. R. Cross was born there 83 years ago, and was educated at Crewkerne Grammar School. Thence he went as scholar to King's College, London, and qualified as M.R.C.S. in 1871. The next seven years were variously and usefully employed in clinical and academic appointments. He was house surgeon at King's College Hospital and resident medical officer at St. Pancras Dispensary; he was evening lecturer in physiology, assistant demonstrator in anatomy, medical tutor, and sub-dean at King's College. Though he attended the Royal London Ophthalmic Hospital as clinical assistant, it was as lecturer on anatomy that he went back to the Bristol Medical School, and it was as a general surgeon that he joined the staff of the Bristol Royal Infirmary in 1878. Elected full surgeon in 1879, he carried on general work for six years, and then resigned to take up the new post of hon. ophthalmic surgeon. Here he managed his department with ability and served the Infirmary well, both professionally and as an organiser. Although he left the active staff in 1900, he continued his association with the hospital, and became vice-president in 1919. He also did a great deal for the Bristol Eye Hospital, where he was surgeon for a long period, and for the Royal School for the Blind. At the same time, through his connexion with Bristol Medical School, he played an important part in the foundation of Bristol University. He was lecturer and subsequently reader in ophthalmology, and fittingly received the honorary degree of LL.D. He was also elected a Fellow of King's College, London.

MR. RICHARDSON CROSS.

[*Photograph by Lafayette.*

From an early stage in his career Mr. Cross was a notable contributor to the journals of his specialty, and sound work soon earned him a distinguished place among his colleagues. He was elected a member of the Council of the Royal College of Surgeons of England in 1898, and served in this capacity until 1914, when he took office as president of the Ophthalmological Society of the United Kingdom. He delivered the annual oration of the Medical Society of London in 1901, the Bradshaw lecture of the College of Surgeons in 1909, the Long Fox lecture at Bristol in 1915, and the Doyne lecture at Oxford in 1920. In his relations with societies and their members, as in his practice and social life, he was as happy in manner as in intention. As a surgeon, perhaps he owed his success not so much to his own original work as to his ability to assimilate what was sound and useful in the practice of others. He was tall and finely built, with a charming voice, and his patients instinctively knew that he was a kindly man. He inspired them also with confidence. This and a shrewd judgment enabled him to get done what was required in serious ca and to ensure that his directions were carried out.

A man of sound common sense, Cross was elected to a large number of the more important pub offices in the city of Bristol. He was Sheriff of Bristol in 1897, and was formerly president of the Grateful Society and the Dolphin Society, and a member of the Council of Clifton College. A ke sportsman, he long followed the Duke of Beaufor hounds, and latterly took much interest in the breeding of stock.

Mr. Cross married in 1889 Eva, daughter of Capt Hawkes, R.N. She died in 1920, and they le three daughters.

MEDICAL NEWS

University of Oxford.

On July 19th the following degrees were conferr

M.Ch.—T. H. Sellors and B.G. Scholefield.

B.M.—G. H. Bateman, F. Bicknell, H. de B. Kempt R. B. Scott, T. R. Plummer, H. S. Atkinson, R. D. Newt R. R. Bomford, Elizabeth C. M. Brunyate, Olive M. Capp Johnson, and (Mrs.) Winifred Pitkin.

University of Cambridge.

Mr. David Keilin, Sc.D., F.R.S., at present universi lecturer in parasitology, has been elected to the Qui professorship of biology, for three years, in succession to Dr. G. H. F. Nuttall, F.R.S., who retires on Oct. 31st Dr. Nuttall has held the professorship since 1906 when it was founded. It is laid down that the professor sha devote himself to the study of parasitology.

Royal Faculty of Physicians and Surgeons of Glasgow.

At the meeting of the Faculty on June 1st the following were admitted to the fellowship: Amar Chand Bhardwa (Simla), John Aloysius McCann (Liverpool), and William Patrick (Glasgow).

University of London.

At a meeting of the Senate on July 15th, Mr. Cyril Lodowic Burt, D.Sc., was appointed to a university chair of psychology tenable at University College.

The Rogers prize of £100 was awarded to Dr. R. W. Fairbrother.

At recent examinations the following candidates were successful:—

DIPLOMA IN PSYCHOLOGY.

Hilda Bristol, Rachel M. Creed, Annie M. Gibson, Margaret A. Leiper, Annie D. Paterson, Doris F. Robinson, Jugal Singh, Jeannette B. Shaw, and Diana V. Spearman.

DIPLOMA IN BACTERIOLOGY.

Dora C. Colebrook, Catherine B. Hendry, C. O. Karunakaran, A. R. Martin, *A. E. Oxford, F. W. Priestley, W. D. B. Read, George Robinson, and Pauline C. Witherow.

* Awarded a Mark of Distinction.

nlversity of Durham.

At recent examinations the following candidates were ccessful :—

M.D.—C. F. Fairlie, George McCoull, L. F. O'Shaughnessy *t absentia)*, T. S. Severs, G. E. Stephenson, H. G. Ungley, H. Wear, and J. H. Weir.

M.D. for Practitioners of 15 years' standing.—J. W. Irvine.

M.B., B.S.—Hugh Bannerman, W. C. D. Bewick, Robert wley, J. I. M. Black, T. H. Boon, Gladys M. Brice, J. L. Burn, F. Down, W. P. Dunn, W. L. Gardner, J. W. Gibson, John les, T. R. Harlan, H. F. Harvey, N. V. Hepple, A. R. Holtby, D. Kelly, J. J. H. Lowe, Elizabeth S. Malcolm, Eileen G. rshall, J. A. McKeon, J. C. Moor, E. W. Peet, A. H. Penman, de W. Ranken, L. R. Routledge, Cathleen Rowstron, Edward ith, and H. K. Vernon.

B.Hy. and D.P.H.—Bertram Sergeant.

L.D.S.—J. A. Atkinson and A. D. Hitchin.

niversity of Liverpool.

The following awards have been made :—Lady Jones search Fellowship in Orthopædic Surgery : E. N. Wardle, B. John Rankin Fellowship in Anatomy : G. W. Causey, B. Johnston Colonial Fellowship in Biochemistry : W. Brookfield, M.D. John W. Garrett International llowship in Bacteriology : Honora J. Twomey, M.B. l Fellowship in Pathology : D. H. Collins, M.B. Holt llowship in Physiology : C. L. G. Pratt, M.D. Thelwall omas Fellowship in Surgical Pathology : R. A. Furniss, B. Robert Gee Fellowship in Human Anatomy : T. E. bnon, M.B. Samuels Memorial Scholarship (Medicine) : A. Birch, M.D. Samuels Memorial Scholarship (Surgery) : Silverstone, M.B. Dr. N. E. Roberts Prize (Zymotic eases) : S. Alstead, M.D. Owen T. Williams Prize : L. Hughes, M.B.

iversity of Leeds.

r. William Gough, F.R.C.S., has been elected professor ynæcology, and Mr. Andrew Moynihan Claye, F.R.C.S., essor of obstetrics in the university.

rse on Circulatory Disorders.

Post-graduate Course on Diseases of the Heart and els will be held at the Hôpital Broussais, 96, rue Didot, s, XIVe, from Oct. 5th to 17th; under the direction r. C. Laubry. Particulars may be had from Dr. Matton e hospital.

s Beatrice Hospital.

Kensington, Fulham, and Chelsea General Hospital en renamed the Princess Beatrice Hospital.

Bartholomew's Hospital and College.

The old students' annual dinner is to be held on Thursday, . 1st, in the Great Hall of the hospital at 7 for 7.30 P.M. Percival Hartley will preside.

e late Dr. C. A. Porter.

Dr. Charles Allen Porter, emeritus professor of surgery Harvard University, whose death is reported from ston, will be remembered in this country as the surgeon charge of the hospital unit which Harvard presented to eat Britain and sent over to France in 1915. He came of distinguished family which has given medical practitioners New England since 1625.

ternational Union against Tuberculosis.

The annual meeting of the council of this union, whose airman is Prof. Frölich (Norway), was held in Paris on uly 9th and was attended by delegates from 17 countries. t was decided that the next conference of the union should e held at the Hague from Sept. 6th to 9th, 1932, and hat the three following subjects should be inscribed on the genda : The Relationship between Allergy and Immunity ; old-therapy ; and After-care Schemes for the Tuberculous. The scientific session was held at the Pasteur Institute, in e new tuberculosis laboratories which the members of the ouncil visited under the guidance of Prof. Calmette. The meeting was devoted to the report of Dr. Soper (United tates) on A Standard Antituberculosis Plan ; in Dr. oper's absence his report was read by Prof. Opie. Prof. altis (Greece) explained the steps taken in regard to the ntituberculosis campaign in his country. These reports were followed by a discussion in which Prof. Léon Bernard, Secretary-General of the Union, Prof. Knud Faber (Denmark), Colonel Rudzki (Poland), and others took part. On the same evening the members of the council dined at the Indo-Chinese pavilion in the Colonial Exhibition, where they were the guests of the French national committee for the campaign against tuberculosis. M. Blaisot, Minister of Public Health, gave an address of welcome.

Fellowship of Medicine and Post-Graduate Medical Association.

From August 4th until the end of the month a course in urology will be held at the All Saints' Hospital. It will include demonstrations and cystoscopies, and will occupy the afternoons and some evenings. The Queen's Hospital for Children is giving an all-day course from August 17th to 29th, instruction being entirely by demonstration of cases. During September courses will be given at the Brompton Hospital (from Sept. 7th for one week), the Bethlem Royal Hospital (Sept. 8th to Oct. 3rd), the Infants Hospital (Sept. 14th to 26th), the Central London Ophthalmic Hospital (Sept. 14th to Oct. 10th), the Westminster Hospital (Sept. 14th to 26th), and the Metropolitan General Hospital (Sept. 28th to Oct. 10th). Detailed syllabuses may be had from the Fellowship of Medicine, at 1, Wimpole-street, London, W. 1.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

THE following appointments have been made: Surg. Lts. R. A. Graff to *Vivid* for Plymouth Hospital; J. H. Nicolson to *Erebus;* and C. R. Boland to *Effingham.*

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lts. E. E. Henderson and F. A. McLaughlin to be Surg. Lt.-Comdrs.

Proby. Surg. Lt. W. B. Wilson to be Surg. Lt.

ROYAL ARMY MEDICAL CORPS.

Maj. J. W. Houston retires on retd. pay on account of ill-health.

Maj. (prov.) G. E. MacAlevey from the secd. list, is restd. to the estabt.

Lt. E. H. Hall to be Capt. and remains secd.

Lt. P. V. MacGarry to be Capt.

The undermentioned Lts. (on prob.) from the secd. list are restd. to the estabt.: J. T. Robinson and J. M. Gibbon.

ARMY DENTAL CORPS.

Lt. R. W. Mather to be Capt.

TERRITORIAL ARMY.

F. R. Langmaid (late Offr. Cadet Serjt., Univ. of Lond. Contgt., Sen. Div., O.T.C.) to be Lt. with seniority.

John O'Donnell to be Lt.

INDIAN MEDICAL SERVICE.

Lt. (on prob.) D. C. Chopra to be Capt (prov.) (on prob.).

Lt.-Col. J. Anderson retires.

ROYAL AIR FORCE.

O. M. Fraser is granted a short service commission as a Flying Officer for three years on the Active List.

RESERVE OF AIR FORCE OFFICERS.

Flight Lt. T. M. Walker is employed with the Regular Air Force for a further year.

The *London Gazette* announces the appointment of Surg. Vice-Admiral R. St. G. S. Bond, C.B., as an Honorary Physician to The King as from July 1st.

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, July 27th, to SATURDAY, August 1st.—MILLER GENERAL HOSPITAL, Greenwich-road, S.E.10. Intensive course in general medicine and surgery. Second week. Daily 10.30 A.M., to 5.30 P.M., demonstrations, lectures, operations.—Further particulars from the Fellowship of Medicine.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.

MONDAY, July 27th.—10 A.M., Genito-Urinary Operations, Skin Department. 11 A.M., Surgical Ward Visit. 2 P.M., Surgical Ward Visit, Medical, Surgical, Eye, Gynæcological Out-patients.

TUESDAY.—9.30 A.M., Operations. 10 A.M., Medical Ward Visit, Dental Department. 11 A.M., Throat Operations.

11.30 A.M., Surgical Clinical Demonstrations. 2 P.M., Medical, Surgical, Throat, Out-patients, Operations, Medical Ward Visit.

WEDNESDAY.—10 A.M., Medical Ward Visit, Children's Medical Out-patients. 2 P.M., Medical, Surgical, and Eye Out-patients. Gynæcological Operations. 4.45 P.M., Venereal Diseases.

THURSDAY.—10 A.M., Neurological Department. 11.30 A.M., Treatment of Fractures. 2 P.M., Medical, Surgical, and Eye Out-patients. Genito-Urinary Department. Operations.

FRIDAY.—10 A.M., Medical Ward Visit, Skin and Dental Departments. 12 noon, Medical Lecture. 2 P.M., Medical, Surgical, and Throat Out-patients. Operations.

SATURDAY.—9 A.M., Throat Operations. 10 A.M., Medical Ward Visit, Surgical and Children's Medical Out-patients.

CHARING CROSS HOSPITAL MEDICAL SCHOOL POST-GRADUATE COURSE.

SUNDAY, July 26th.—10.45 A.M., Mr. C. Jennings Marshall: Hæmaturia: Its Significance and Investigation. 11.45 A.M., Dr. A. A. W. Petrie: Adolescent Psychoses.

ST. MARK'S HOSPITAL, City-road, E.C.

THURSDAY, July 30th.—4.30 P.M., Mr. W. B. Gabriel: Anal Fissure.

Appointments

FREEMAN, ERNEST A., M.B., B.S. Lond., F.R.C.S. Eng., has been appointed Fracture Officer and Orthopædic Surgeon to the Royal Hospital, Wolverhampton.

MITCHELL, J. G., M.B., Ch.B., N.Z., Certifying Surgeon under the Factory and Workshop Acts for Hednesford, Stafford.

MONCRIEFF, ALAN. M.D. Lond., M.R.C.P. Lond., Honorary Physician for Diseases of Children to Bolingbroke Hospital, Wandsworth.

SIMPSON, A. S., M.B., B.S. Lond., Medical Officer of Health for Stalybridge.

STOTT, W., M.B., B.S. Durh., Medical Officer of Health for Southwark.

Vacancies

For further information refer to the advertisement columns.

Aberdeen Royal Infirmary.—Jun. Asst. Surgeon.
Accrington, Victoria Hospital.—H.S. £150.
Acton Hospital, W.—Jun. Res. M.O. £100.
All Saints' Hospital for Genito-Urinary Diseases, Finchley-road, N.W.—H.S. At rate of £150.
Altrincham General Hospital.—Sen. and Jun. H.S. At rate of £150 and £100 respectively.
Bangor, Carnarvonshire and Anglesey Infirmary.—H.S. £200.
Barnsley, Beckett Hospital and Dispensary.—H.P. £200.
Bath, Royal United Hospital.—Sen. H.S. At rate of £175.
Bedford County Hospital.—Asst. H.S. At rate of £130.
Benenden, Kent, National Sanatorium.—Res. Asst. M.O. £300.
Birmingham, Midland Hospital, Easy-row.—H.S. £150.
Bootle General Hospital, Nr. Liverpool.—H.P. At rate of £150.
Bradford Children's Hospital.—H.P. £120.
Bradford Royal Infirmary.—Three H.S.'s. Each £150.
Bury Infirmary, Lancs.—3rd H.S. At rate of £150.
Brighton, Royal Sussex County Hospital.—Cas. H.S. £120.
Brighton, Sussex Eye Hospital.—Hon. Clin. Asst.
Bristol, Stoke Park Colony.—M.O. £600.
Chester, East Lancashire Tuberculosis Colony, Barrowmore Hall, Great Barrow.—Asst. M.O. At rate of £275.
Chesterfield and North Derbyshire, Royal Hospital.—H.S. At rate of £150.
City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—H.P. At rate of £100. Also Registrar.
Coventry, Coventry and Warwickshire Hospital.—Res. Cas. O. £125.
Dudley, Guest Hospital.—H.S. and Asst. H.S. £200 and £170, respectively.
Durham County Hospital.—Two H.S.'s. Each £150.
East Ham, County Borough of.—Asst. M.O. £500.
Exeter, Royal Devon and Exeter Hospital.—H.P. and H.S. to Special Depts. Each at rate of £150.
Folkestone, Royal Victoria Hospital.—Locum Tenens Res. H.S.
Gravesend and North Kent Hospital.—Jun. H.S. £100–£150.
Great Yarmouth General Hospital.—H.S. £140.

Sheffield Royal Infirmary.—H.S. and Second Asst. Cas. O. Ophth. H.S. Each at rate of £80.
Staffordshire, Longton Hospital.—H.S. £120.
Swindon and North Wilts Victoria Hospital.—Res. M.O. rate of £125.
Walsall General Hospital.—H.P. At rate of £150.
Walsall Manor Hospital.—Asst. M.O. £150.
Warrington Infirmary and Dispensary.—Jun. H.S. £175.
Wolverhampton, New Cross Hospital.—Asst. Res. M.O.
Worcester General Infirmary.—Jun. H.S. £120.

The Chief Inspector of Factories announces vacancie Certifying Factory Surgeons at Egremont (Cumb and at Hillsborough (Sheffield).

Births, Marriages, and Deat

BIRTHS.

DAVIES—On July 18th, at 27, Welbeck-street, the wife Dr. Daniel T. Davies, of a son.

MARRIAGES.

BATT—ROBERTS.—On July 14th, at the Parish Ch Cadoxton, Barry, Dr. John Child Batt, to Mona Edw Roberts, of Cadoxton, Barry.

ECKHOFF—ALLISON.—On July 17th, at Christ Church, Lanca gate, Nils Lovold Eckhoff, M.S., F.R.C.S., to Audrey daughter of the late Mr. T. J. Allison, of Pietermaritzb Natal.

DUNCAN—BUNTING.—On July 18th, at St. John's, Stanm F. W. Kenneth Duncan, L.D.S. Eng., to Florence Lill only daughter of Mrs. Bunting and the late Walter Samp Bunting, of Westgate-on-Sea.

HEATH—FEATHER.—On July 14th, at St. Mary's Church Weaverham, Cheshire, William Edwin Heath, M.B., B.S. to Winifred Maude Feather, M.B., Ch.B.

PRESTON—KING.—On July 21st, at All Saints', Upper Norwood Thomas Warwick Preston, M.D., M.R.C.P., to Marga Mary King.

YOUNG—BALL.—On July 18th, 1931, at St. James', Norlands Dr. George Campbell Young, younger son of the late Mr. John Young and Mrs. Young, of Wimbledon, to Minni Marjorie, youngest daughter of Mr. and Mrs. Ball, of Chesterfield.

DEATHS.

GRAY.—On July 15th, at Loughor, suddenly, Allan Edward Lambton Gray, M.B., C.M. Edin. of Abbotsea, Leamington Spa, aged 66 years.

ROSE.—On July 18th, at a nursing home in Barnet, Captain Percy Rose, L.R.C.P., D.P.H., late R.A.M.C.

TATE.—On July 18th, at The White House, Louth, Lincolnshire, after brief illness, Lieut.-Colonel R. G. H. Tate, R.A.M.C. retired, aged 52.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

MENTAL INEFFICIENCY AND ADOLESCENT CRIME.

By W. Norwood East, M.D., M.R.C.P. Lond.,
ONE OF H.M. COMMISSIONERS OF PRISONS.

(*Concluded from p. 169.*)

The Psychopathic Type.

The constitutional psychic inferiors usually present n prison reactions markedly different from those of he group of psychopathic personalities with whom hey are classified by some observers. Healy,[11] ollowing Adolf Meyer, adopts the term "constitu-ional inferior" rather than "psychopathic inferior," nd places cases of constitutional psychic inferiority etween feeble-mindedness and insanity. I have lready stated that this condition appears to me to e between mental deficiency and normality; and ses of psychopathic personality, as we see them prison, seem to me to occupy a position between nsoundness of mind and normality. I suggest, in ther words, that the qualities of the constitutional ychic inferior which affect criminal conduct are gative, and those of the psychopathic personality e positive.

Ziehen [12] includes in his definition of psychopathic rsonalities a very wide range of cases, embracing, May points out, not only hysteria and neurasthenia t epilepsy. Clouston [13] recognised the group, and luded therein the crank, the markedly eccentric, l the anarchist; the man who easily falls into minal ways; the miser, the chronic drunkard, e asocial and the ne'er-do-well; and the man of rbid wayward impulses possessing much originality much force of character. Kraepelin [14] divides group into several classes: the excitable, the ble, the impulsive, the eccentric, the asocial, hers.

American *Psychiatric Association Committee* cribes psychopathic personalities as a large group pathological personalities whose abnormality is pressed mainly in the character and intensity of heir emotional and volitional reactions. It specifi-ally excludes feeble-minded individuals, and calls tention to the fact that the constitutional psychoses ise on a basis of psychopathic inferiority or con-itution, because the previous mental make-up in hese conditions shows more or less clearly abnor-nalities in the emotional and volitional spheres. here remain, however, other less well-differentiated ypes of psychopathic personalities, and in these the sychotic reactions differ from those in the preceding roups. It is these less well-differentiated types of motional and volitional deviation which are to be esignated, at least for statistical purposes, as sychopathic personalities. The type of behaviour isorder, the social reactions, and the trends of interest, which psychopathic personalities may show give special features to many cases—e.g., criminal traits, moral deficiency, tramp life, sexual perversions, and various temperamental peculiarities. The Com-mittee further point out that the mental disturbances or psychoses which develop in psychopathic personali-ties are varied in their clinical form, and are usually sporadic in character. Most frequent are attacks of irritability, excitement, depression, paranoid episodes, and transient confused states, and the Committee place the prison psychoses in this group.

Dr. August Wimmer,[15] in a personal letter, describes the group as follows:—

"A psychopath or constitutionally psychopathic person is an individual, the social maladjustment or antisocial or criminal trends of whom are due not to real defects of intelligence (as in feeble-mindedness), but to an anomalous mode of emotional and instinctive reaction and to behaviour troubles resulting therefrom. His psychic anomalies are habitual, very often manifesting themselves from early childhood, and mostly due to hereditary influences. His abnormal psychic outfit is rather constant during his lifetime, even if showing some fluctuation in connection with, for instance, menstruation, puberty, climacterium, and it is only to a certain degree influenced by environmental conditions—e.g., social, educational, and prison life. Along with the psychic troubles are often found other biological or nervous disturbances, manifesting the organic substratum of the psychopathy—e.g., developmental irregularities, retardation of physiological ripening, troubles of sleep, and convulsive conditions, more or less hysteriform or revealing the aspect of affect epilepsy or the like. Very often the psychopaths will more episodically, or in a more phasic way, manifest isolated or more psychotic symptoms as syndromes—psychogenic psychosis."

Prof. Wimmer adds that he considers a long definition necessary to avoid confusing the cases with mild stages of real mental disease.

The psychopathic personality may be associated with grave crimes or petty offences, and mental abnormality may be suggested by the circumstances of the antisocial act. These offenders are often characterised in prison by forceful, hostile, stubborn, violent, and reckless conduct; and they sometimes exhibit transient phases of excitement or depression. We see them often irritable, quarrelsome, impulsive, suspicious, untruthful, vain, and conceited; they may be impervious to argument and difficult of approach. Their reactions are persistently opposed, and in some particular direction, to the organisation of their environment; they may repeat the same crime in an attempt to impose their will on others, and their conduct is frequently detrimental to their own welfare. They sometimes swallow foreign bodies and refuse food, they make frivolous complaints, and exaggerate subjective sensations. Their outlook is selfish and narrow, they lack insight into their condition, and their judgment is biased. But they are shrewd, cunning, alert, energetic, and capable, and their memory, attention, perception, and capacity for sustained effort may be good. This type of offender is frequently under observation in prison, and may develop mild persecutory ideas or insane delusions. It is characteristic of the condition that the delusions tend to disappear when the individual is at liberty, and to reappear after reconviction.

The diagnosis of this cause of mental inefficiency may be conjectural in adolescent offenders, but the passing years display the symptoms of the fully declared condition.

A lad, 19 years of age, was convicted of warehouse-breaking in association with a man some years older than himself. His history showed that he was sent to live with his grandmother when two years old, and was accompanied by two elder brothers. At the age of 14 he unwillingly returned to his parents, and twice stole from his father the exact railway fare back to his grandmother. He was detained for four years in a reformatory, where he was happy and conducted himself well. On discharge he returned home and obtained several occupations which he soon left, and he was thought to be lazy. He was not solitary; he played cricket, football, and billiards, and owned a motor cycle. His home was a good one, but his parents frequently quarrelled. On examination I found him alert, independent, and rather brusque in manner. He was of fair average intelligence and his memory, attention, and perception were good. He professed great affection for his grandmother, and less for his mother. He was definitely hostile to his father; he considered that it was wrong to send him from home when so young, and also wrong to send him to his parents after he left school. He believed his father was prejudiced against him, as he reported the thefts to the police, and would not let him remain out late at night, although his brother, aged 25, was allowed to do so. He was affronted because his father allowed his sister to read harmless books, but tore up the detective stories he brought home. His outlook on life was somewhat defiant; he was obstinate, jealous, and suspicious, and entertained ideas of persecution. His initiative and energy were directed towards crime as a result of his social maladjustment. The inability to deal with his emotional conflicts in a satisfactory manner, and the resulting paranoidal reactions, suggested a constitutional psychopathic make-up. It remains with the future to declare whether the efforts to divert him from crime will meet with success, or whether he will continue prejudiced and inefficient, a slave to the tyranny of his organisation.

The Psychoses.

The authorities quoted and actual prison experience show that manic-depressive disorder may arise in psychopathic personalities as well as in individuals who, after the normal emotional level has been regained, present no mental peculiarity other than the tendency to recurrence of the cyclothymic reaction. In criminal cases, as elsewhere, it is important to distinguish between the two types of case, for the psychopathic personality remains at a constant disadvantage and may commit further offences as a result, although rid of the manic-depressive episode.

In adolescents the milder phases of mental excitement or depression, seen so frequently in delinquents, may suggest adolescent instability rather than cyclothymic disorder. But, broadly speaking, the emotional phase in the latter is one either of exaltation or depression, and is more or less continuous for the time being, and the resulting conduct is compatible with the current emotional state. In adolescent instability the emotional reactions are mixed, and are unaccompanied by the continuous press of activity of the hypomanic patient or the continuous diminution of psychomotor response of the hypomelancholic. And although, in the early stages of mania, emotional hyper-excitability is liable to rapid and successive changes, the accumulation of symptoms as the disorder proceeds soon demonstrates its severity and distinguishes it from the less intensive condition of adolescent instability. The mildest degrees of mental exaltation and depression are not infrequent causes of temporary mental inefficiency in adolescents, and may be worsened if corrective efforts are misdirected or misapplied. If the slight cyclothymic deviations from ordinary conduct are recognised and appraised, the criminal adolescent can be assisted to regain his normal mental level and efficiency.

In the severe forms of schizoid reaction the cause of the mental inefficiency is so obvious that it is unnecessary for us to consider the cases at length. But we see in certain criminal adolescents inefficiency arising from mental symptoms, minor in degree, but of the præcox type. The subjects show slight loss of interest in their environment, they may be idle at work and disinclined for games, they may have an ill-defined sense of inferiority, be somewhat unsociable and preoccupied, and appear incapable of sustained effort. Some are inclined to be suspicious, hesitating, and hostile to authority and control. In others, slight vagaries of thought, feeling, and action may present themselves from time to time; trivial happenings may excite disproportionate reactions and whimsical conduct result from passing fancies. But the individual symptoms are only slight exaggerations of those usually associated with adolescence, and only call for a legitimate extension of the latitude and toleration usually permitted to youth. They indicate collectively only a slight departure from a state of adequate adjustment.

Some of these cases can be observed to progress, and present later the clinical features of dementia præcox. Some remain unchanged, although under observation for prolonged periods. The symptoms may resemble, for a time, those seen in certain cases of high-grade feeble-mindedness, particularly defectives who are developing the præcox syndrome. But not a few re-establish their social contacts and regain and apparently maintain their mental health, and it seems proper to regard them as examples of the minor and recoverable grades of dementia præcox to which Mapother,[16] Henderson and Gillespie,[17] Devine,[18] and others have directed attention. Recovery may be aided by patient, prudent, and sympathetic encouragement, by obtaining the subject's coöperation to readjust his difficulties, and by attention to his general health. It is important also to remember that Beaton,[19] in discussing the treatment of early cases of dementia præcox, warns us that "it is unwise in these acute adolescent disturbances to permit of any systematic psychological investigation; analysis in the Freudian sense has, in the experience of most psychiatrists, been productive of more harm than good, and it is certainly unnecessary."

Hysteria and Anxiety.

The symptoms usually presented by the hysteric delinquent before trial are mutisms, fugues, amnesias, and fits. But sometimes the psychic inefficiency is shown by emotional explosions, or the imitation of some striking anti-social act which has received undue publicity. These morbid mental phenomena permit the individual to assert himself, and arouse the interest and compassion of his audience. They are obtruded and outlined in a manner the hysteric believes to be accurate and recognisable; and, although they become exaggerated in a sympathetic environment, there is no conscious attempt to deceive and no conscious motive for the symptoms. They are the solution of his mental conflict, and express his incompetency to deal with unfavourable circumstances.

After trial the hysterical exhibitions of convicted prisoners are perhaps more frequently physical than mental. Occasional examples of the latter are seen in delinquent girls who shut themselves in their rooms and set them on fire, or insert needles in their breasts and limbs. We meet them again in male offenders, youths, and occasionally men, who swallow foreign bodies. In many of these cases we can trace ment conflict, and the suggestibility of the offender is show by the frequency with which he copies the misdirecte efforts of an associate. Further, the calm ment attitude described by Janet in cases of hysteria often present; and although the subjects are clea anxious to assert themselves, and desire to a interest and invoke sympathy, they reject the prob consequences of their self-inflicted injuries. Evide of the hysterical nature of the symptoms recei additional support from the fact that they pa when the environment is changed. I have alr called attention to the fact that many offenders who swallow foreign bodies are psychopathic personalities. Vanity prompts others to attempt to secure the admiration of their fellows by these means. Some who require repeated abdominal sections to remove a succession of foreign bodies are reckless criminals, prepared to go to any length to cheat justice and gain their ends. It is not so long ago that their prototypes placed their limbs under railway trucks to avoid work, or shattered a finger to escape oakum-picking.[20]

Mild anxiety states may be the cause of abnormal fatigability of obscure origin in adolescent offenders. The natural disinclination of youths to admit fear, and their inability to appreciate the limitations imposed by anxiety, often make it particularly difficult to elucidate the symptoms associated with their social inefficiency. The prison physician must go out to meet the patient, who is unlikely to refer to his difficulties spontaneously. But seldom are cause and effect so clear as in the following case:—

A youth was convicted for breaking into a pavilion, and had been previously convicted for theft. He left one situation for no apparent reason, although he was earning 65s. a week at the time. He appeared to be depressed, reserved, diffident, and lacking in self-confidence. He wandered from home, slept out, and was the despair of his parents, who were unable to understand his eccentricities until he confided his troubles to them by letter, being too shy to speak openly about them. He was in good physical health, but it was clear that he had been anxious about his bodily condition for a long time, and thought that an imaginary bodily deformity and his habit of blushing made him conspicuous and ridiculous to strangers in the street. The mere thought of appearing in public produced a panic which was met by a phobia so overwhelming that he could only go out when it was dark, or during the day if enveloped in a large macintosh.

And, although he was able to attend a week-end camp by means of this expedient, he was unable to stir out of his tent. He described how he repeatedly went to his own front door to start to look for work, and was then overcome with panic and returned, although his mother sometimes went to the door with him to encourage him to greater efforts. He was a good worker, and believed that if he had obtained night-work he would have been able to retain it. But, as things were, he looked forward to detention in prison or a Borstal Institution as the best solution of his difficulties. He was of average intelligence and his memory was fair, but he was encumbered by a sense of his own inferiority, was easily fatigued and unable to concentrate, and his sleep was disturbed. His facial expression was anxious and depressed, and reflected clearly his emotional state. He had some insight into his condition. He underwent a course of psychotherapy and regained confidence in himself, and the anxiety and depression appeared to pass off. But when last heard of there was reason to suppose that the symptoms had returned.

The compulsion neuroses need be mentioned only to be dismissed. They are readily distinguished from the impulsive actions of defectives and from other causes of mental inefficiency if their paroxysmal characters and accompaniments of resistance and distress are called to mind. Some psycho-therapeutists admit that these cases are among the most intractable in the whole range of psychotherapy.

Fatigability.

There is perhaps no single condition so frequently associated with mental inefficiency and adolescent crime as a disinclination for work due to indolence and fatigability. Fatigability may be a symptom of mental deficiency, but in some juvenile offenders indolence appears to be an independent and innate constitutional disposition, probably comparable to the indolence of certain primitive races whose wants are few and easily satisfied. It is exhibited in others as a habit of mind which has been acquired as the result of precept, example, or circumstance. G. H. [illegible][21] has pointed out how wrong-placement, inadequate training, and an unsympathetic supervisor tend to dull enthusiasm so that work and everything associated with it has, in time, so many accumulated associations of harshness, discomfort, and inadequate that it is shunned. Indolence results in the postponing the commencement of his task as long as possible, and leaves him unexhausted when the work is completed. He expends a minimum of energy, and if the matter in hand is unfinished he is unconcerned, as he is unable to appreciate the satisfaction of accomplishment. Nevertheless, he often succeeds at play, for he may undertake this with enthusiasm and energy. He sleeps well and is not necessarily irritable, although he often displays temper when forced to work.

Mental fatigability, which I suggest is to be distinguished from indolence, may be associated with various conditions: with physical disease, endocrine imbalance, sexual and other excesses, mental deficiency and mental disorder, and psychological reactions to conscious difficulties or repressed conflicts. It is of recent development in the life of the patient and, although it may restrict his capacity for work, is not inconsistent with ambition. Moreover, failure causes disappointment, if the subject is concerned with results and covets fulfilment. Unlike the indolent adolescent, he tires at play as quickly as at work, for his energy is soon exhausted. Moreover, he often sleeps badly, and may be irritable generally.

William Brown,[22] writing in 1926, leads us to consider that reliable results have been obtained by skilful hands in the measurement of mental fatigue. But William McDougall,[23] writing in the same year, insists that the results of experimental studies of fatigue, up to date, are meagre, chiefly because the energy of the human organism is conditioned by the physiological state at the time of the experiment, and because the varying factors of incentives and motives are beyond control. C. S. Myers [24] has directed attention to the fact that the ergogram is favourably influenced by increased interest, pleasure, or other mental excitement. Laboratory tests, therefore, seem inadequate materially to assist the clinician to arrive at the ætiological factors which lower the threshold of fatigue. This is unfortunate, for the distinction between indolence and abnormal fatigability is important when dealing with adolescent delinquents. Here, as elsewhere, the detection of initial causes and their removal, when possible, is the first step in treatment. Then follows, for the indolent, incentive, example and reward; for the fatigued, suggestion, encouragement, and graduated progress; for both, the presentation, at the opportune moment, of the fact that purposive striving is a problem which must be faced before social efficiency can be attained. Probably no harder task is imposed upon the guardians of adolescent criminals than the conversion of firmly established indolence into efficiency if the subject is also slightly below the average in mental capacity, but above the level of mental deficiency. The following is an example:—

A youth, 17½ years old, was charged with vagrancy. He had been previously bound over for shopbreaking in company with another lad, and occasionally slept out. His father was dead, his mother was a respectable, hard-working charwoman. He was thought to be dull at school, but on leaving went as little-piecer in a mill and remained at the same employment for 15 months, in spite of the fact that the work was distasteful and the placement at fault. He did no regular work after this, except during four months in one situation, although permanent employment was offered him. The police did not consider his tendencies were criminal, although he was an idle frequenter of street corners. His general health was good, his height was 66 in., and his weight, 132 lb., was normal for his age and height. He was below the average in intelligence, and his mental age was 11 years. But he was fairly well-informed on matters of ordinary interest and common knowledge, although his performance tests, judgment of shapes, memory for designs, mechanical ability, and manual dexterity were probably below the average for his class. He lacked ambition and perseverance, and complacently confessed to being lazy. His aim in life seemed to be to get as much excitement out of it with as little effort as possible. But none of the experienced medical men through whose hands he passed found sufficient evidence to support a certificate of mental deficiency.

Adolescence is the age of surprises, and various factors combine to produce mental inefficiency and crime. I have endeavoured throughout to keep in close contact with clinical problems, and this is essential to the nature of our work. For our material is elusive: inferiority may be associated with crime or genius, the same conscious difficulties may produce opposite effects in different individuals, repression may be associated with criminal conduct, but without repression coöperative power is lost and society as we know it is impossible. Moreover, the problems are complex: psychiatry and psychology throw much light upon them, but other methods of approach are important also, notably the sociological, biological, anthropological, and eugenic. We must not confuse a part with the whole. Mental deficiency is an important factor in producing mental inefficiency, and we should resist any attempt to make it the dumping-ground for all adolescent non-effectives. It is for us to recognise slight deviations from normal conduct and endeavour to set them right. To do this we must ascertain as far as possible their origin and probable causes and effects. Some of our cases, like the unstable adolescents, may be guided safely through this difficult period. Some, like certain psychopathic personalities, may remain irresponsive. Some, like the mild cyclothymes, may reach the phase of normal conduct unassisted. All provide material for study and research. In our dealings with adolescent criminals, as well as in our own affairs, we must remember McDougall's admonition: "The really difficult thing in life is to have the stoicism that comes with realisation of the vanity of human wishes, and to combine it with energetic purposes and keen zest in the striving to accomplish them: to look at yourself and your affairs in a large and humorous way, and yet be urged on to constant effort by the divine discontent; to be at once stoic, epicurean, and keen worker. Yet, unless you can be all these together, you will not have made the most of life."[25]

MEDICAL EDUCATION IN THE SUDAN.

THE Kitchener School of Medicine, Khartoum, has just issued its third report, covering work done in the years 1928–1930. It was founded in 1924 with the object of building up a cadre of Sudanese doctors to combat the epidemic and endemic disease of their country, to bring medical assistance within reach of all the inhabitants, and ultimately to replace medical men imported from abroad. The course takes four years, followed by a year at one of the larger hospitals in a house appointment; the abbreviation is secured by compressing the teaching of anatomy and physiology into a single year and omitting from it everything not definitely essential to the subsequent instruction. The school works on a small scale, and individual attention can be given that almost amounts to personal tuition. The yearly output aimed at is six qualified men, and the first-year class is maintained at ten students, carefully selected from the Gordon College. Seven doctors graduated in 1928 and seven more in 1929; all of these are now medical officers, and six are in sole charge of small hospitals, performing entirely satisfactory work. Five more have graduated this year, and are still on probation in house appointments. The success of these pioneers has made a great impression on students at the Gordon College, and there should now be no difficulty in getting recruits from the best type. The establishment of chemistry and biology classes at the Gordon College has enabled a more thorough grounding in these subjects to be given during the first year, and close liaison between the two bodies has been established in many directions. The new medical research laboratories, established opposite the school in 1928, have facilitated the teaching of pathology and now work in close coöperation with the school and the Civil Hospital. The experiment is interesting, for the students belong to a primitive people which little more than a generation ago was sunk in barbarism and misery. They are, however, virile, teachable, and capable of great enthusiasm and devotion. A country is more influenced by its medical profession than perhaps by any other movement, and the school ought to play an important part in the development of the Sudan.

TOBACCO TOLERANCE IN FISH.

Léon Binet and C. Zamfir record[1] experiments made on fresh-water fish in order to determine whether tolerance to tobacco and nicotine could be established. The tobacco was administered in the form of a maceration fluid made by soaking 2 g. of Maryland tobacco in a litre of river water for 24 hours, stirring occasionally, and finally filtering. The experiments were carried out in vessels containing 600 c.cm. of river water to which the fluid had been added in varying proportions. Three goldfish were prepared by exposure to water to which was added maceration fluid in gradually increasing strength, from 7·5 per cent. to 22·5 per cent. in 51 days. The fish were alternately exposed for 24 hours and rested for 24 hours in a large tank of running water. After this preparation they survived exposure to concentrations which killed unprepared fish in an hour, and after 66 days' preparation they even survived exposure to undiluted maceration fluid for three-quarters of an hour. Similar results were obtained with solutions of nicotine up to 0·003 c.cm. of the pure alkaloid in a litre of water. As, however, no investigation was made into the possible after-effects of the experience, smokers should not be too ready to draw the conclusion that tobacco in any quantity is harmless once a tolerance is established.

A PATIENT'S VIEWS ON TUBERCULOSIS.

A BOOK[1] *written by a layman* who has himself had tuberculosis, and feels that much of his suffering might have been spared if he had been dealt with frankly by his doctors in the earlier stages, is worth attention. The writer is an American, and the book i essentially American in its outlook. The autho evidently had an unfortunate beginning to hi experience as a phthisical patient. In the introduction, he says that, although he consulted and wa examined by a number of physicians, none of the ever seemed to appreciate the sinister nature of th disease, and none of them ever gave him a parti of helpful advice. He has, therefore, set out t produce a book "by a layman, for laymen, and wi the layman's point of view," in the hope that it ma bring about a better understanding of the disease an its problems in the mind of the patient.

The book is a good comprehensive survey of th tuberculosis problem from the patient's standpoi It is written in a crisp, arresting style, and contai much good advice. The medical profession con for a good deal of candid criticism—for exam "Much harm is constantly being done by i criminate and ill-advised surgery, or surgery th undertaken too soon. There is a time to operat *a time not to operate*, and it requires experien with the disease to make the proper decision."

The author writes feelingly about so-called cure "The disease lends itself well to every kind of 'cure and remedy under the sun, providing there is plen of rest mixed up with it. After one becomes tuber cular, it seems that half of the people one meets kno *of a certain remedy or form of treatment* that the claim 'cured' some relative of theirs or someone the knew."

On the question of sunlight, real or artificial, the author expresses the sound view that it should never be used except upon the advice and under the supervision of experienced physicians and technicians. He has good advice to give to his fellow-countrymen on the choice of places to live in, such as Colorado, California, and the Pacific Northwest. The final chapter contains some helpful remarks to ex-patients on occupation, especially to those who have been compelled by their disease to change their job.

[1] *Tuberculosis: its Cause, Prevention, and Care.* By Frank H. Livingston. New York: The Macmillan Company. 1930. Pp. 191. 10*s.* 6*d.*

STANMORE OBELISK.—The Royal National Orthopædic Hospital's branch at Stanmore, Middlesex, stands upon part of the ground where in 54 B.C. the most powerful British tribe, the Catuvellauni, under Cassivellaunus, checked the Roman advance on S. Albans. About the year 1760 a local resident erected an obelisk to commemorate the victory and placed Latin inscriptions upon it. The obelisk, which had fallen into bad condition, has just been restored by the committee of the hospital and the inscriptions replaced.

ADDRESSES AND ORIGINAL ARTICLES

ON VACCINE THERAPY AND IMMUNISATION IN VITRO.*

BY SIR ALMROTH WRIGHT, K.B.E., C.B., M.D., D.SC. DUB., F.R.S.,

PRINCIPAL OF THE INSTITUTE OF PATHOLOGY AND RESEARCH, ST. MARY'S HOSPITAL; PROFESSOR OF EXPERIMENTAL PATHOLOGY IN THE UNIVERSITY OF LONDON.

THE methods of combating infections in the organism can be divided up into (*a*) those which aim at removing or extirpating the microbes by mechanical means; (*b*) those which aim at killing the microbes by the agency of chemical antiseptics; (*c*) those which make use of the antibacterial powers which already exist in the organism, but do not concern themselves with increasing these; and (*d*) those which aim at developing increased bactericidal powers in the blood or passively supplementing these powers.

It will be useful to preface what I have to say about vaccine therapy by a brief survey of the alternative methods of treatment.

Methods of *surgical extirpation* may be distinguished into incomplete operations which confine themselves to the removal of a conspicuous focus of infection, and those which aim at the complete eradication of an infection combined with an excision of a *locus minoris resistentiæ*.

Operations of the former kind were only a few years ago extensively employed in surgical tubercle. They were resorted to upon the idea that the organism would, when the full weight of the infection had been taken off, be competent to cope with the germs that are bound to be left behind. This optimism was, of course, more often than not disappointed, the operation being frequently followed by a recrudescence of the infection. This, in point of fact, is just what might have been expected. For operations upon infected foci must always carry with them a risk of producing a negative phase of diminished antibacterial power and favouring the spread of the infection.

Similar dangers attach to enucleation operations of the kind which leave open raw surfaces. Here, if the resistance of the organism is reduced, reinfection from outside is likely to follow.

Treatment by Antiseptics.

The history of antiseptic treatment is the history of what has followed from the erroneous assumption that chemical agents which kill microbes when brought into application in water will do the same when brought into application in serum-impregnated tissues, suppurative discharges, and blood. The ordinary medical man deems that assumption to be somehow right, and he fails to see any reason why it should not be. And he feels sure that if the assumptions he made were wrong, clinical observation would very quickly bring this out.

That confidence is quite misplaced. Probative evidence of the harmfulness of a treatment is furnished only when the clinical condition of a patient becomes conspicuously worse after the application of a treatment, and this happens again and again. Similarly probative evidence of the efficacy of a treatment is furnished only when the clinical condition of a patient is indubitably better after treatment, and this happens repeatedly. In every other case clinical observation leaves us in incertitude as to whether a method of treatment is doing a modicum of good, or a modicum of harm, or is doing neither good nor harm.

Once these inherent limitations of clinical methods are realised it becomes obvious that we must, if medicine is to make steady advance, find some method of distinguishing treatment which is in an inconspicuous manner useful; from treatment which is in an inconspicuous manner harmful; and from treatment which does neither harm nor good.

The first thing to lay to heart here is that it is hopeless to trust in such matters to our unaided senses, and that it is in the case of antiseptics fallacious to draw inferences from the clinical condition of the patient or the condition of a wound. If we seriously want to arrive at the therapeutics of a bacterial infection we must do two things.

First, we must experiment upon simpler biological complexes—complexes such as the blood or the pus or inflammatory fluids derived from a focus of infection, or, better still, upon separated blood fluids, transudation fluids, and leucocytes.

Secondly, we must, in order to discover the event of a therapeutic intervention, have recourse to laboratory technique and scientific apparatus.

Let me give a concrete illustration of the kind of therapeutic problem which I have here in view.

As an incident in an enterprise of research undertaken in 1911, with the aim of alleviating the formidable mortality from pneumonia in the mines of the Transvaal, I and my fellow-workers had, *inter alia*, to inquire into the utility of the internal administration of antiseptics, a method of treatment which was in vogue in some of the mine hospitals.

We had here to elect between two procedures—statistical inquiry into the results of treatment being one method; and inquiry into the effect exerted by antiseptics upon the pneumococcus suspended in serum being the other.

Let us consider what the former method of inquiry would have involved. It would have involved, first, obtaining control over the treatment in the mine hospitals. It would have involved choosing one particular antiseptic and one hard and fast scheme of dosage for all the cases, and imposing this upon all the medical officers. It would have involved further the carrying out of the experiments upon a very large number of cases, and arranging for a corresponding number of similar cases to be left untreated. It would have involved also the keeping of medical histories of all the cases and the verification of the diagnoses by post-mortem examinations of all who died.

Again, and this is a very important consideration in connexion with statistical inquiries into any treatment which is believed in by some observers and dissented from by others (and that was the case here), there is in all such cases a very strong presumption that the treatment in question is in reality not very effective, and that the figures when they shall have been arrived at will exhibit a difference too small to be convincing.

Finally, if the aforementioned considerations do not clearly bar the method of statistical inquiry, one has to consider the length of time and the formidable number of patients which would be required for settling by statistics even a single item in a programme of treatment—for example, the superiority of one antiseptic over another, or of one scheme of dosage over another.

---

* Based on an address to the Medical Society of London on Oct. 27th, 1930.

From all this it is apparent that the method of statistical inquiry is utterly impracticable, and that it would, if this were the only method available to us, be necessary to abandon all hope of determining whether a particular treatment is in some degree helpful; or in some measure harmful; or leaves things just as they are. There remains, however, the alternative of recourse to laboratory experimentation.

ON THE APPRAISEMENT OF THE VALUE OF ANTISEPTICS BY LABORATORY METHODS.

The earliest, or among the earliest, experiments on the question as to whether antiseptics can be turned to account in the treatment of bacterial infections, would appear to have been those of Koch. It was shown by him that though sublimate in a dilution of 1 in 1,000,000 inhibited the growth of anthrax in nutrient gelatin, sublimate in double that concentration does not in any way modify the course of anthrax infection in rabbits. Behring showed that this found its explanation in the fact that a dilution of 1 in 10,000 of sublimate was required to restrain the growth of anthrax in serum. And calculation shows that to achieve such a 1 in 10,000 concentration of sublimate in the blood fluids of a 70-kilo man it would (assuming these fluids to measure 2500 c.cm., and assuming also the full quantum of sublimate administered to come into application) be necessary to administer intravenously 0·25 g. of sublimate —i.e., about grs. 4.

Our experiments were carried out in essentially the same way as those of Behring. Graduated dilutions of antiseptics were made in water, on the one hand, and serum on the other, and then in each case the same quantum of pneumococcus culture was implanted. The details of these experiments are set out in my book entitled The Treatment of Pneumonia by Drugs and Vaccines (Constable, London, 1914). The upshot was that while lysol, creosote, and guaiacol—the three antiseptics experimented with—kill the pneumococcus in very high dilutions in water they would, for killing the pneumococcus in the patient's blood, have to be administered intravenously in frankly poisonous doses—in the case of lysol in a dose of over 75 minims and in the case of both creosote and guaiacol in a dose of 15 minims.

We now come to some further points in connexion with the testing the efficacy of antiseptics by *in vitro* experimentation. In particular, it must be realised that while the method of measuring of the bactericidal power of an antiseptic upon microbes implanted into serum is infinitely superior to the method of measuring the bactericidal power upon microbes suspended in water, it is, nevertheless, a method which fails to take into regard many very important physiological considerations.

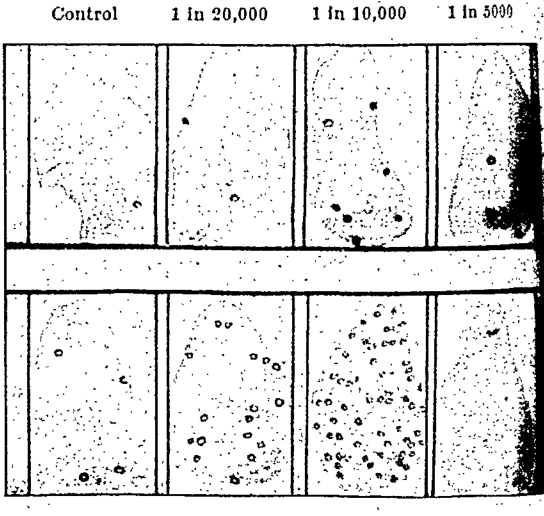
My friend and fellow-worker, Prof. A. Fleming,[1] has very properly insisted that antiseptics which are destined for use in the blood should be tested upon microbes implanted into blood; and similarly, that antiseptics designed for use in a wound should be tested upon microbes contained in or implanted into pus.

Fleming further pointed out that antiseptics may be usefully tested by implanting staphylococcus into serum without and with antiseptics and incubating measured quanta of such sera in capillary tubes lined with emigrated leucocytes and, for purposes of control, also in ordinary unlined capillary tubes.

The apparatus and technique employed in these testings having been elsewhere described,[2] I may deal directly with their results. And those experimental results can be most conveniently shown in the form of diagrammatic pictures.

Fig. 1 shows the effect of adding in slide cells an ordinary antiseptic to blood implanted with staphylococci. Infinitely more can be learned from an experiment of this kind than was learned from experiments in which microbes are implanted into serum. The experiments which I made by that method in South Africa taught us only that creosote, guaiacol, and lysol and such antiseptics do not kill microbes immersed in serum. From these of Fleming we learn that antiseptics added to blood in small doses render the blood more congenial to microbic growth, and that they, when added in the largest doses that could be used therapeutically, convert the blood into a medium in which serophytic microbes grow unrestrained. (These results are due to the antiseptic entering into destructive chemical combination with the leucocytes.) Finally we learn here, as in experiments such as those we made in Africa, that bactericidal effects are achieved only where frankly poisonous doses are resorted to.

FIG. 1.



Carbolic Acid. Effect on staphylococci in blood. Equal volumes (25 c.mm.) of infected blood and dilution of antiseptic. 25 c.mm. of blood plated on agar gave 56 colonies.

Exactly the same lessons are taught by Fleming's marvellously simple and ingenious experiments with pus. In Fig. 2 it is seen that a non-corrupted pus taken from a wound and kept from drying (by placing it on a moist agar surface under a cover-glass) possesses not only sufficient, but (as other experiments show) more bactericidal power than is needed to kill such numbers of microbes as are ordinarily contained in it. And the figure shows that when half per cent. carbolic acid is added to such pus its bactericidal power is forfeited—this being, as in the case of the carbolised blood, due to a poisoning of the leucocytes.

Fig. 3 again enforces the same lesson. Here carbolised and non-carbolised sera are implanted in each case with staphylococcus. In Fig. 3 A where the staphylo-implanted serum has been cultivated in tubes lined with emigrated leucocytes we see that the umber of colonies which develop increases as more ind more carbolic acid is added—this result being as n the other experiments attributable to a poisoning of he leucocytes by the antiseptic.

[1] Proc. Roy. Soc. B., 1924, xcvi., 171.

[2] Most of it in my "Technique of the Teat and Capillary Tube," second edition, Constable, London, 1921.

In *Fig. 3* B *where precisely the same sera are culti*-ated in unlined capillary tubes we see that the umber of microbes which grow out into colonies is he same in all the tubes. In other words, carbolic cid in strengths up to 1 in 400 fails to nhibit the growth of staphylococcus n serum.

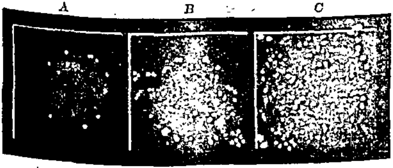
Chemotherapeutic Agents or Endohæmic Antiseptics.

Having taken these things to heart, e may now pass to the consideraon of the antiseptics which Ehrlich yled—I venture to think very unfornately—*chemotherapeutic agents*. wo things about that designation trike me as unfortunate. The prime bjection to the term is that it does ot make clear that Ehrlich meant by chemotherapeutic drug: an agent hich would enter into destructive emical combination with microbes the organism. The second objection the term is that every active drug d vaccine has an indefeasible claim be called a chemotherapeutic agent. view of this I would propose to ll the drugs Ehrlich called chemoerapeutic agents *endoseric*, or *endohæmic, antiseptics*, and to call the dinary antiseptics, for distinction, *ectoseric*."

OPTOCHIN.

With this I resume the account of experiments made in South Africa 11. After finding that medicinal ta of lysol, creosote, and guaiacol ere incompetent to kill pneumococci blood, I proceeded to make trial optochin—a quinine derivative hich had, in the hands of Morgenoth, given very striking results in he treatment of mice infected with highly virulent pneumococcus. Morgenroth's results pointing, as it seemed to me, to ptochin being an endoseric antiseptic—I commenced perations by adding it in graduated doses to serum mplanted with pneumococci. These experiments howed that optochin exerted a bactericidal effect upon pneumococci in serum, and that it exerted this effect in serum and in water indifferently in all dilutions up to 1 in 400,000.

FIG. 2.



(A) A drop of wholesome uncorrupted pus obtained from a wound was here implanted upon an agar plate and incubated under a cover-glass. Here all the microbes were killed excepting a few which have grown out into colonies in the film of fluid pressed out from the pus by the weight of the cover-glass.

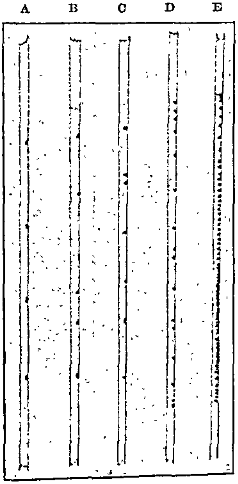
(B) A similar drop of pus which had been heated to 47° C.

(C) A similar drop of pus which had received an addition of 1 in 300 carbolic immediately before it was imposed upon the agar plate.

Similar experiments showed that optochin exerts *this bactericidal effect specifically upon the pneumo*coccus. Ordinary ectoseric antiseptics exert their effect upon microbes without distinction of kind.

We further found that the serum of animals and man was bactericidal for the pneumococcus for at least five hours after the ingestion of optochin.

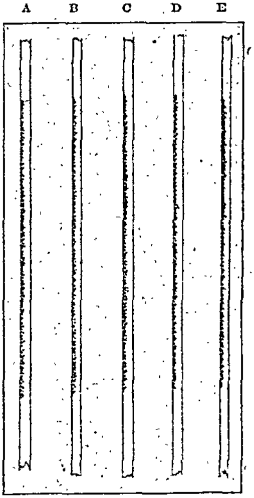
FIG. 3A.



Leucocyte-lined capillary tubes filled in in each case with serum containing the same charge of staphylococcus and in the case of (B) (C) (D) and (E) an addition of carbolic acid.

(A) Serum with no carbolic.
(B) ,, ,, 1 in 3200 carbolic.
(C) ,, ,, 1 in 1600 ,,
(D) ,, ,, 1 in 800 ,,
(E) ,, ,, 1 in 400 ,,

FIG. 3B.



Unlined capillary tubes filled in in each case with the same charge of staphylococcus and in the case of tubes (B) (C) (D) and (E) an addition of carbolic acid.

(A) Serum with no carbolic.
(B) ,, ,, 1 in 3200 carbolic.
(C) ,, ,, 1 in 1600 ,,
(D) ,, ,, 1 in 800 ,,
(E) ,, ,, 1 in 400 ,,

These findings were confirmed by Schiemann[3] in 1915. *His experiments* showed that the pneumococcus implanted into citrated blood was killed by optochin employed in dilutions as high as 1 in 1,000,000.

There are not sufficient clinical data for deciding definitely upon the value of optochin in the treatment of human pneumonia *for, owing to the drug affecting* the patient's eyesight, experimentation with it had everywhere to be broken off. The therapeutic effect would, however, appear to have been, taken generally, disappointing.

SALVARSAN.

Let me now deal with another chemotherapeutic agent, to wit, salvarsan, and its application to the treatment of anthrax, streptococcus, and staphylococcus infections.

With regard to the anthrax bacillus, the experiments of Schiemann showed that salvarsan exerts in dilutions such as can be obtained in the blood by the exhibition of a *dosis tolerata* a bactericidal effect upon this microbe. His experiments further showed that it takes with such high dilutions a number of hours to effect the destruction of the anthrax bacillus.

---

[3] Zeits. f. Immun. Orig., 1915, xxiv., 167.

The history of the idea that salvarsan might exert a bactericidal action upon the streptococcus in the body is as follows: That salvarsan might possibly exert a bactericidal effect not only upon the spirochætes of syphilis which were Ehrlich's special target, but also upon the associated streptococcal and staphylococcal infections suggested itself to me in treating cases of rupia with one of the earliest samples of 606. What specially impressed me was the almost magical disappearance of the streptococci from the sequence of cultures made from the lesions of patients under treatment. To test the possibility of this being due to a bactericidal action exerted directly upon the streptococcus I proceeded next to administer 606 to a case of malignant endocarditis. That case, like other cases, ended fatally, but the results were so far favourable that for a time the patient's temperature regularly came down after each injection of 606.

Later on the question as to whether the blood fluids become, after the injection of 606, bactericidal to the staphylococcus, was investigated and answered in the affirmative by experiments made by two of my fellow-workers, S. R. Douglas and L. Colebrook.[4]

Later researches made by Colebrook[5] in connexion with the bactericidal effect exerted upon the streptococcus brought out the following facts:—

(1) The variety of streptococcus which is most sensitive to the bactericidal action of salvarsan is the *Streptococcus hæmolyticus.* The others are much less sensitive to the drug administered in medicinal doses.

(2) The blood is, by the intravenous injection of salvarsan, rendered more bactericidal to the *Streptococcus hæmolyticus.* The same result is obtained by adding the drug in similar concentration to the blood in vitro.

These results do not, as was pointed out by Colebrook, mean that salvarsan is not poisonous to leucocytes. It means only that the drug, when employed in medicinal concentrations, is less poisonous to the leucocytes than it is to the streptococcus.

A further important finding which concerns these results must now be noted. Colebrook—like Schiemann, in working with anthrax—found that salvarsan when employed in medicinal doses in serum kills streptococcus only after operating upon them for three hours. Now this means, of course, that salvarsan must, if it is to do any good, continue to circulate in the blood in adequate concentration for that minimum number of hours. Convincing *in vitro* proof that it does so must always be difficult to obtain. What requires in this connexion to be borne in mind is that if a sample of blood drawn off and tested after intravenous injection contains arsenic in effective quantities, that is not in itself conclusive. For the arsenic content in a blood sample which is tested in vitro continues unchanged while the arsenic in the circulating blood may be in steady decline.

It follows from the fact that data with regard to the amount of arsenic in the blood and the rate of elimination in the blood are with difficulty accessible that the utility of salvarsan in the treatment of bacterial infections must in the last instance be determined by clinical experiment.

Favourable results have been reported from the use of the drug in anthrax, and this furnishes ground for hope that success may be obtained also in the treatment of streptococcal infections; and further ground for hope is furnished by the fact that Colebrook, by a course of [illegible] eous inoculations of arsenicals, has been able to keep the strepto-bactericidal power of the blood at a high level for several weeks.

Conclusions Relating to Chemotherapy.

Let me now try to summarise the outcome of this, I am afraid, long-drawn discussion. Two things in particular have come out clearly:—

(1) The first is that a bactericidal and sterilising action in the organism can be looked for only from drugs which can be used in concentrations which exert a bactericidal action in the serum and blood in vitro, and it is futile to expect any advantage from the exhibition of drugs which abolish the bactericidal action of leucocytes.

(2) It is likewise futile to expect a bactericidal and sterilising effect in the organism from the exhibition of such endohæmic antiseptics as are both slow in action and vanish very quickly from the circulation.

In obedience to these principles we must cross of the list of intravitam endohæmic antiseptics, no only all the ordinary familiar antiseptics, but also large number of drugs which are or have been reput chemotherapeutic agents.

We must cross off to begin with *sanocrysin* whic was, in despite of the fact that it fails to kill th tubercle bacillus when used in a 1 in 500 concentratio in serum, bruited abroad as a chemotherapeu remedy for the treatment of tuberculosis. We m further, despite the fact that *optochin* kills the pneum coccus in the blood in very high dilutions, cross off our list for the reason that it is gravely poisono Further, we must cross off *mercurochrome,* for th drug added to serum and blood in the highest conce trations which would be permissible in the organis fails to exert a bactericidal effect.[7] We must furth cross off from the list of chemotherapeutic agent *flavine* and *gentian violet,* for these dyestuffs, thoug they are both endohæmic antiseptics, are eminent slow in their action, and vanish very quickly from t circulation.

If we question ourselves what remains of the che therapy of bacterial diseases proper when all the ab items have been crossed out, our answer must be apparently only salvarsan and its congeners rem We have seen with regard to these that they increase the bactericidal power of the blood to anthrax bacillus and the *Streptococcus hæmolytic* and that they may perhaps remain in the circulati in sufficient concentration long enough.

This general conclusion is very important when w ask ourselves exactly how much can be done by methods other than vaccine therapy in the treatment of bacterial infections.

Kataphylaxis.

Before I pass on to consider what can be done by vaccine therapy it will be well perhaps to gauge what can be done by other procedures which aim at killing microbes by what I have ventured to call *kataphylactic* measures, that is measures which determine to the focus of infection the bactericidal powers resident in the blood fluids and leucocytes. Examples of what I have called kataphylactic measures are the opening up of abscesses, the evacuation of infected discharges, the application of Bier's bandages and of hot compresses, all kinds of radio- and helio-therapy, and the drawing out of corrupted serum from an infected surface by the agency of hypertonic salt solution. These methods are in every case of service. But when all is said and done the degree to which they are useful in the particular case depends upon the antibacterial potency of the blood—this being the reservoir of antibacterial power which every kataphylactic measure draws upon. This may be illustrated by the fact that the opening up of a localised tuberculous focus when the bactericidal power of the blood is below par does very little towards extirpating the infection while such a measure is more effective when the antituberculous power of the blood is well above par.

Principles of Vaccine Therapy.

I pass now to the subject matter proper of this discussion—the employment of vaccines for the purpose of enhancing the antibacterial power of the blood in infected patients.

Let me—for it is axiomatic that every therapeutic measure should repose upon a sound theoretical basis—begin what I have to say about vaccine therapy by harking back to its intellectual foundations, and *justifying principles*. The principle of vaccine therapy is the same as that of Pasteur's antirabic inoculations. Pasteur gave intellectual countenance to his antirabic inoculations by pointing out that a man who has been bitten by a rabid animal may in the interval between the implantation of the virus and the development of overt symptoms be quite properly classed as uninfected, and that he may consequently, with propriety, be preventively inoculated.

That was the principle to which I gave extended application by pointing out that all localised infections may be conceived of as precursors (generally, of course, abortive precursors) of septicæmic infections. And the way I pictured the situation to myself was that, so long as an infection remains localised, the infected tissues combat the infection unaided, the uninfected tissues remaining in the meanwhile passive and idle. Picturing things to myself in that way led *inevitably to the thought* that it would be possible by the aid of vaccines "to turn to account the interest of the infected tissues the unexploited immunising faculties of the uninfected tissues."

In formulating that principle I had in view under the denomination of "tissues," the "fixed tissues." I meant, so far as I meant anything precisely, the subcutaneous tissues into which the vaccine was inoculated and the various cellular organs with which the vaccine would, after absorption, come into contact. I would now propose to replace the term tissues in the above formula by the term leucocytes. That proposed change of wording is dictated by the consideration that conclusive evidence (some of this I *propose* to adduce) has been *obtained* of the elaboration of antibacterial substances by leucocytes, while we have, despite every sort of search, failed to find any indication of the generation of antibodies by the fixed tissues.

With that I pass to another point. When *it is* claimed for therapeutic procedure that it will enhance the antibacterial power of the blood, that contention should in every case—I need hardly say how very rarely this is even attempted—be confirmed by evidence obtained by laboratory methods. To comply in the case of vaccine therapy with this requirement it was necessary to devise new methods of blood testing. This was necessary because the method of testing the bactericidal power of the serum which I had devised for use in connexion with antityphoid inoculation is inapplicable where we are dealing with serophytic microbes, such as the staphylococcus and streptococcus.

The Opsonic Index.

It was to meet this new requirement my late friend and fellow-worker, W. B. Leishman, devised his method for measuring the phagocytic power of the blood. And the method for measuring the opsonic power of the serum, which was an outcome of Leishman's method, was also devised in the service of vaccine therapy.

Without these methods it would, except only in cases in which inoculation produces dramatic improvement or dramatic exacerbation of symptoms, have been impossible to decide whether a dose of vaccine was *doing good or harm, whether it should be increased* or diminished, and after what interval inoculation should be repeated.

But the guidance furnished in treatment of individual cases was not, as a matter of fact, the chief intellectual profit gained from our measurements of the opsonic index. (We made for many years 30,000 to 50,000 of such measurements annually at St. Mary's.) We learned from those measurements *principles that seem to me to lie at the very foundations of medicine.* Let me enumerate them.

(1) To begin with, we learned from these measurements that a succession of negative and positive phases such as I had described [8] in connexion with typhoid vaccination occurred when any vaccine was inoculated in quantity sufficient to produce appreciable constitutional disturbance. With regard to the negative phases, I had already in connexion with prophylactic inoculation pointed out that a negative phase means a temporarily lowered resistance to bacterial attack, and that, therefore, a negative phase should never be induced in a patient who is living in infected surroundings. The same principle holds *a fortiori* of a patient who is already the subject of an infection. Here the induction of a negative phase may lead to an exacerbation and a dissemination of the infection.

(2) The second general principle which was learned from measurements of the opsonic index (and Dr. John Freeman took a conspicuous part in the initiation and development of this research) was that *auto-inoculation* (the term had to be invented) can be artificially evoked by a large variety of procedures, and may also occur automatically. Such auto-inoculations produce negative and positive phases in exactly the same way as inoculations of vaccine.

We further learned in connexion with auto-inoculations that they can be produced in patients by active and passive movements, and by sending an ampler lymph stream through an infected focus (the so-called *stagnation method* of Bier). Further, that they can be produced by helio-therapy, radio-therapy, and the application of heat. And we learned also, quite early in our investigations, that automatic auto-inoculations occur whenever a patient who is the subject of an extensive infection is allowed out of bed. Finally, it was in this connexion brought home to us that in a progressive infection such as phthisis—the same applies, of course, to all acute infections—there sooner or later supervenes a stage when the biography of the patient—even when he is kept completely at rest—resolves itself into a succession of spontaneous auto-inoculations. It is the signal merit of Dr. Marcus Patterson to have applied these principles to practice in the treatment of phthisis, and to have realised that success depends largely upon the regulation of the auto-inoculations by the regulation of exercise, and to have appreciated further that the most rapid and effective remedial treatment for pyrexia produced excessive auto-inoculations is absolute immobility in bed.

(3) A third advantage—and this was, of course, a

---

[8] Treatise on Antityphoid Inoculation. Constable, London 1904.

question of purely practical as distinguished from theoretical importance—gained from our innumerable measurements of the opsonic index undertaken before and after inoculations undertaken upon patients, was that we learned what quanta of the various vaccines can be administered to slightly infected and non-pyrexic patients without risk of inducing a negative phase.

(4) The fourth advantage gained from our measurement of the opsonic indices of patients was that through these there was formulated a general schema or principle of dosage. The all-important principle which was arrived at is that the dose of vaccine administered to a patient should be inversely as the number of microbes affecting (i.e., delivering antigen) into his circulating blood. In other words, we should in constitutional infections give only minimal doses of vaccine; should give intermediate doses to patients suffering from a strictly limited local infection; and should exploit large doses which produce negative phases only in healthy patients and for prophylaxis.

OPSONINS AND PHAGOCYTOSIS.

Having shown what important principles were learned from our measurements of the opsonic power of the blood-serum, I turn to the question whether we have in the opsonic index a true measurement of the phagocytic power of the blood.

My original idea—based upon investigations carried out with S. R. Douglas [9]—was that the opsonic index furnished a true measure of the phagocytic power of the blood. That conclusion was arrived at by taking from our out-patients (these were non-pyrexic and, therefore, probably non-auto-inoculating patients) bloods with high and bloods with low opsonic indices, and comparing the leucocytes of these bloods with those of our own bloods. We employed for that purpose what I have since called the *chiastic procedure.* That procedure consists of digesting with a microbic suspension: (1) the patient's washed corpuscles used in conjunction with his own serum; (2) his corpuscles used in conjunction with a normal serum; (3) washed normal corpuscles used in conjunction with normal serum; and (4) these corpuscles used with the patient's serum. The event of these operations carried out on our out-patients showed that in their case the amount of phagocytosis was determined almost entirely by the serum, and hardly at all by the corpuscles employed in the phagocytic mixture.

Afterwards S. G. Shattock and L. Dudgeon corrected these observations. They employed melanin granules instead of microbes, and carried out the tests upon pyrexic and auto-inoculating, instead as we had done upon patients who were non-pyrexic and, presumably, non-auto-inoculating patients. Shattock and Dudgeon's [10] investigations clearly demonstrated that the phagocytic avidity of the leucocyte is a variable factor, and that the phagocytic avidity of a patient's leucocytes may sometimes be much greater and sometimes much less than that of the normal leucocytes. Their investigations—their results were, as already mentioned, obtained with melanin granules—further established that phagocytic efficiency is a non-specific function of the leucocyte. These fundamentally important observations show that opsonic power is, at any rate, in pyrexic cases, a fallacious measure of the phagocytic power of the blood.

We have in the fact that the phagocytic avidity of leucocytes may suffer change a possible explanation of our having often found very high opsonic power in patients dying of phthisis. Examination might have shown these high indices to have been counterpoised by diminished phagocytic avidity. For in following up the observations of Shattock and Dudgeon we have found that the general rule in severe bacterial toxæmia is for the efficiency of the patient's leucocytes to be low while his opsonic index is high. It is easy to see a possible causal connexion between these two findings. The leucocytes may deplete themselves of antibacterial elements by parting with these to the blood fluids.

I now pass to an issue even more fundamental than that which was raised by Shattock and Dudgeon. We may ask ourselves whether a measurement of the phagocytic power furnishes in any case an adequate measure of the antibacterial power of the blood. That question must be answered in the negative. And our answer must be in the negative—*first,* because the leucocytes can kill bacteria not only intracellularly, but also extracellularly, by excreting bactericidal elements into the surrounding fluids; and *secondly* (and Douglas [11] has examined this question in detail), because phagocytosed microbes may fail to be digested in the leucocytes of one blood while they are in the leucocytes of another blood rapidly digested.

It follows that we cannot, if we wish to arrive at a true measure of the antibacterial power of the blood, content ourselves with measuring phagocytic power. We must measure the actual bactericidal effect exerted.

(To be continued.)

THE TECHNIQUE OF INTRALARYNGEAL INJECTION OF LIPIODOL,

WITH DESCRIPTION OF SPECIAL APPARATUS,

BY W. J. FENTON, M.D. CAMB., F.R.C.P. LOND
CONSULTING PHYSICIAN, CHARING CROSS HOSPITAL, PHYSIC
TO THE HOSPITAL FOR CONSUMPTION AND DISEASES
OF THE CHEST, BROMPTON.

LIPIODOL is a combination of iodine and poppy-seed oil containing 40 per cent. of the former. It is of a pale amber colour and medium consistency when cold but thins considerably at the body temperature. It is non-irritating and is comparatively rapidly absorbed from the lung tissue. Occasionally it gives rise to iodism, but not so often as might be expected from its large iodine content. It is opaque to the X rays, and this property renders it, when injected into the bronchi, of the greatest value in the diagnosis of certain conditions of the lungs and bronchial tubes which would otherwise remain unsuspected, or, at best, a suspicion impossible of confirmation. To it we owe a fuller knowledge of certain pulmonary diseases, such as bronchiectasis, neoplasm, and pulmonary abscess, and are able to demonstrate the results of artificial compression of the lung in conditions of cavity formation.

There are two methods of introducing lipiodol into the trachea and bronchi, the most generally favoured of which is direct injection into the trachea through the crico-thyroid membrane by means of a needle and syringe. The other method is intralaryngeal injection after local anæsthesia of the pharynx and larynx has been produced, and is the subject of this paper. I do not propose to enter into a discussion of the relative values of these methods; each has its special utility under suitable conditions.

---

[9] Proc. Roy. Soc., 1903, lxxii., and 1904, lxxiii.

[10] Proc. Roy. Soc. B., 1908, lxxx., 165.

[11] Proc. Roy. Soc. B., 1916, lxxxix.

There are, however, certain advantages associated with the intralaryngeal route. It is simple and well tolerated by nervous patients. Indeed, those who have been the subject of both procedures have expressed themselves strongly in its favour. The discomfort is very transient, and the procedure can be repeated almost indefinitely; one patient received six injections consecutively. It can be quickly performed, and the percentage of failures is very small. It is also free from the suspicion of "operation," is devoid of danger, and becomes a diagnostic routine.

It is probable that the intralaryngeal route has not found the favour it deserves owing to the absence of a satisfactory technique of general application, and the difficulty that has been experienced in producing effective anæsthesia of the larynx. On investigating this method it soon became evident that, if anæsthetisation of the larynx could be satisfactorily accomplished, all the rest would follow, the actual manipulation requiring little more than sufficient skill to use a laryngeal mirror in the left hand whilst the injection is made by a syringe held in the right. Attempts have been made to allow the oil to trickle into the larynx without the use of the mirror, but the result is uncertain, and usually the major part of the lipiodol is found in the stomach, instead of in the bronchi.

A Series of Cases.

The following list includes a series of patients upon whom the intralaryngeal route has been practiced

MEN.

In this list of cases bronchiectasis was demonstrated, except where otherwise stated.

No.	Chief symptoms.	Daily sputum.	No. of Injects.	Remarks.
	Cough and hæmoptysis.	2 oz.	2	Successful.
	Cough.	3 ,,	2	,,
	Silent.	0 ,,	1	,,
	Cough.	3 ,,	1	,, Negative.
	,,	½ ,,	1	Successful.
6	Cough and hæmoptysis.	20 ,,	1	Successful. Neoplasm.
7	Cough.	1 drm.	1	Successful.
8	,,	½ oz.	1	Successful. Failed through neck.
9	Silent.	0	1	Successful. Blocked bronchus.
10	Cough.	1 oz.	1	Successful. Chronic bronchitis.
11	,,	2 drm.	2	Successful.
12	,,	1 ,,	1	,,
13	Silent.	0	1	,, Negative.
14	Cough.	2 oz.	1	Successful.
15	,,	3 ,,	1	Not entirely successful.*

* Anæsthesia not complete.

WOMEN.

No.	Chief symptoms.	Daily sputum.	No. of Injects.	Remarks.
1	Hæmoptysis.	0	1	Successful.
2	Cough.	Very small.	1	,,
3	,,	2 drm.	1	,,
4	,,	3 ,,	1	,,
5	,,	¼ oz.	6	Successful. Simple bronchial stenosis.
6	,,	3 drm.	2	Nervous: failed first time. Second time successful.
7	,,	1 oz.	1	Successful.
8	,,	6 ,,	1	,,
9	,,	1 ,,	1	Failed. Very nervous. Swallowed persistently.
10	,,	½ ,,	1	Successful.
11	,,	1 ,,	2	,,
12	,,	1 ,,	2	,,
13	,,	2 ,,	1	,,
14	Silent.	0	1	,,
15	Cough.	5 oz.	1	,,
16	(See below*).			Failure.
17	Cough.	¼ oz.	1	Successful.

* Patient highly nervous and would not open her mouth.

The series includes 32 cases—15 men and 17 women—who, between them, have had 43 injections. There were three failures, two of which were complete and due to nervousness, while the third was not entirely successful owing to incomplete anæsthesia. Many of these patients were sent into hospital with a diagnosis of pulmonary tuberculosis or for observation and diagnosis under the suspicion of pulmonary tuberculosis. The amount of sputum in many of the cases was small, but in some five, six, and even twenty ounces daily were brought up.

It is worth noting that hæmoptysis was complained of in three cases. In one of these neoplasm was demonstrated; in the other two sputum, physical, and X ray examinations were negative, and not until lipiodol was used could the real condition underlying this symptom be shown—*viz.*, bronchiectasis. This finding supports the view, based upon other examinations of the same kind, that some cases of hæmoptysis in which physical signs are entirely absent, and in which an X ray examination has been also negative, are not due to tuberculosis, but to bronchiectasis, and that this origin for the blood-spitting must be borne in mind and excluded in cases presenting this symptom before the diagnosis of pulmonary tuberculosis is made. It is probable that as the number of examinations by lipiodol increases this association will be recognised more frequently, and that certain cases of hæmoptysis hitherto regarded as tuberculous must be reviewed in the light of this possibility.

The number of cases in the table is not great, having been confined to those investigated by the method under review, but it is sufficient to indicate that there are few in which the intralaryngeal method may not be confidently expected to be entirely successful. How far it can be applied in children has yet to be shown, but it is unsuited for those below a certain age, when a general anæsthetic is usually necessary.

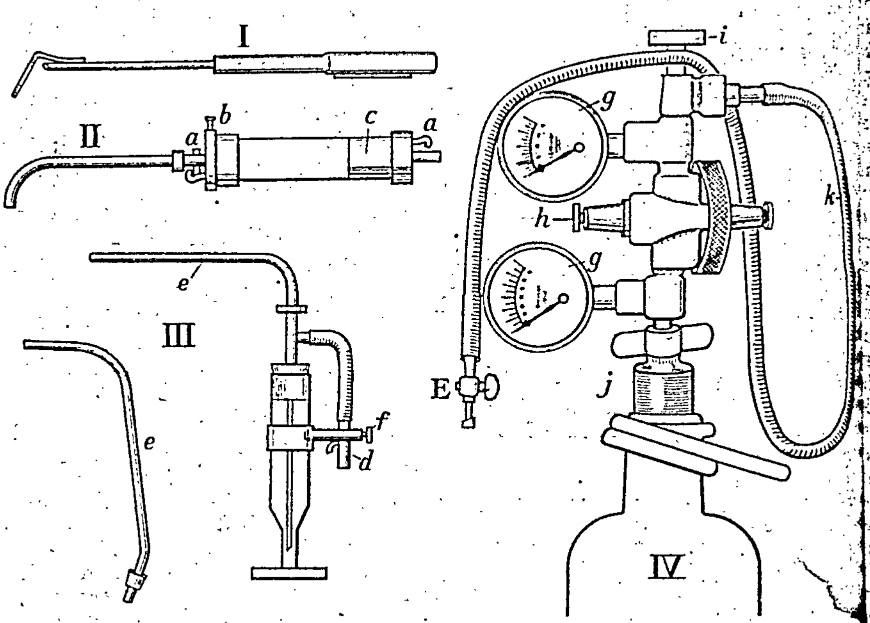
Method of Anæsthesia.

In the earliest attempts to work out a technique, the throat and larynx were anæsthetised with cocaine by means of a swab. This was unpleasant to the patient and caused so much discomfort that, by the time the anæsthetisation was completed, he was not in the best condition to tolerate the introduction of the lipiodol, and it became clear that an entirely satisfactory technique could not be evolved unless local anæsthesia could be produced in some other way. It was accordingly decided to use a specially designed atomiser but, owing to the necessity of holding it in the right hand whilst using the laryngeal mirror with the other, the method required unusual skill and was unlikely to be of general utility. The idea of using compressed air then suggested itself. There were difficulties to be overcome, and various methods were tried, more or less successfully.

Finally, it was found that the ordinary high-pressure compressed-air cylinder could be used quite satisfactorily if suitable conditions were complied with, and its introduction has greatly facilitated the procedure needed to obtain the desired degree of anæsthesia. It has not been necessary to use more than 25 minims of a 5 per cent. solution of cocaine, and of this quantity the major part is spat out of the mouth.

Introduction of Lipiodol.

Anæsthesia having been produced, there remains the problem of introducing lipiodol. This may be accomplished by injecting the oil directly into the trachea by means of an ordinary laryngeal tube and syringe operated by the fingers and thumb of the right hand, whilst the laryngeal mirror is held in the left. In expert hands this is comparatively easy, but to the unskilled in laryngeal work it presents certain difficulties, and to simplify the method I have devised a syringe in which compressed air expels its contents, leaving the fingers entirely free to control the injection. In order to reduce accessory apparatus to a minimum, I have modified the ordinary form of laryngeal mirror with attached electric bulb, to render it more easy of manipulation. It is light, straight, and easily carried, avoids the necessity for a head mirror, and is more comfortable for use by an operator wearing glasses.



I. Laryngeal mirror. II. Lipiodol syringe, showing (*a*) bayonet joints for attachment of laryngea tube extension and two-way tap respectively, (*b*) finger-control valve, (*c*) piston. III. Spra with (*d*) bayonet joint for attachment of two-way tap, (*e*) straight and curved laryngeal tube (*f*) finger-control valve. IV. Compressed air cylinder carrying automatic pressure regulat (*g*) high and low pressure gauges, (*h*) safety valve, (*i*) regulator valve, (*j*) main compress air cylinder valve, with lever folded, (*k*) rubber connecting tube carrying two-way tap which is fitted to the spray or syringe as required.

The details of the apparatus are as follows :—

The compressed air cylinder is controlled by an automatic pressure-regulator which performs the function of delivering the air at a pre-arranged working pressure, and of maintaining it at that level. It is provided with two gauges, one indicating the pressure, and so the amount of reserve air, in the cylinder, and the second showing the working pressure in the delivery tube. A safety-valve, which prevents excessive pressure being accidently produced in the apparatus, is also provided. A rubber tube fitted with a two-way tap and a bayonet joint conveys the air to the atomiser or to the syringe as may be required.

The atomiser consists of a glass container, graduated in minims, and of a narrow bore, which allows it be held at an acute angle without affecting its working. It is provided with two delivery tubes, a straight one to spray the soft palate and fauces, and a curved one for the larynx. It is controlled by a small valve clipped to the glass container and operated by the thumb or finger.

The lipiodol syringe consists of a glass or metal cylinder of the usual pattern fitted with a hollow piston moving freely in its interior. This piston can only be removed from the rear end of the syringe, a flange having been left at the forward end in order to prevent its accidental expulsion.

Screwed on to the barrel of the syringe are two metal end pieces, the one in front carrying a valve controlling the expulsion of its contents, whilst that at the rear is provided with a bayonet joint for attaching the two-way tap. The latter placed in the " on " position admits air to the piston, and when turned " off " cuts off the air supply and places the barrel of the syringe behind the piston in direct communication with the atmosphere, thus enabling the piston to be returned to the rear end for the purpose of refilling.

The laryngeal tube is removable, and is attached by a bayonet joint. It has not been thought necessary to graduate the syringe, as this tends to weaken the glass and occasionally leads to fracture on slight causes. An ordinary laryngeal mirror with lamp and head reflector can, of course, be adopted, but the special mirror will be found simple to use. Its means of illumination is the small battery contained in the handle, which consists of an ordinary pocket flash-lamp. The battery has a " life " of about two and a half hours if used intermittently, and is always obtainable. It is advisable to keep one or two spare batteries, and when the light begins to fail the battery can be replaced with a fresh one, and will regain its voltage if set aside for 24 hours.

In devising the apparatus I have attempted to make it as " foolproof " as possible, but there are one or two points which should receive attention in order to obtain the maximum efficiency. In assembling the parts of the syringe the flanged end should always be in front, otherwise—should the operator forget to turn off the two-way tap after use—the piston may be ejected when the front end is screwed off to refill. Secondly, unless the two-way tap is turned off when the injection is completed, the piston cannot be returned to the bottom of the syringe to allow of refill or removal. Thirdly, the piston must be inserted solid end first.

The apparatus is used as follows :—

The rubber connecting tube having been attached to the regulator valve, the latter, along with the two-way tap, should be opened. The main cylinder valve should now be opened slowly by gently striking the extended lever with the hand, and when the air begins to flow the two-way tap should be closed and the regulator valve left open. (It is unnecessary to open the main cylinder valve more than is sufficient to maintain a steady working pressure in the automatic regulator gauge.) The two-way tap is now attached by its bayonet joint to the atomiser and turned into the " on " position. The atomiser is used in the ordinary way, and is controlled by means of its own finger valve. When anaesthetisation is finished the two-way tap should be turned off and disconnected from the atomiser.

Meanwhile the front end of the syringe is screwed off, the piston pushed down as far as it will go, and the required amount of warmed lipiodol poured in. The end is now replaced, screwed down just sufficiently to be air-tight; the laryngeal tube, if not already in position, is attached by its bayonet joint, and, care being taken that the rear end is also screwed down air-tight, the two-way tap is turned on. With the syringe held vertically, the valve in front is carefully depressed until all the air is expelled ; the valve is then released and the syringe is ready for use. The precise method of manipulation must be left to individual preference.

When the injection has been made the two-way tap must be turned off, thus releasing the air behind the piston; the front end can now be screwed off, the piston pushed back as far as possible, and the syringe refilled if necessary.

The following technique has been found to give the most satisfactory results : If the patient is bringing up much sputum the bronchi should be previously emptied by instructing him to lean over the side of the bed and to cough, whilst the head and shoulders are held as low as possible. Then the patient sits in a chair *facing the operator*, and it is fully explained to him that the entire procedure is a *simple one*, and any apprehension he may have allayed. The lower teeth are covered with a swab, in order to protect the tongue, which should be *protruded as far* as possible and gently held by an assistant. The soft palate, fauces, and the posterior part of the tongue are sprayed, using the straight tube of the atomiser *for* his purpose. It is then *replaced by the curved* one, he laryngeal mirror is introduced, and the anterior nd posterior surfaces of the epiglottis are carefully prayed. This *done*, the end of the tube is passed own over the epiglottis and the interior of the rynx is sprayed. Passing the tube still further, he vocal cords are similarly treated, and, if thought ecessary, the tube can be passed between the cords, nd the upper part of the trachea likewise sprayed. etween each of these steps the patient should spit ut the superfluous solution.

The atomiser is now replaced by the syringe, preously filled with warm lipiodol, and the patient ld *to cough* and clear his throat of mucus, and terwards to breathe quietly and in the normal anner, leaning towards the side into which is proposed to introduce the opaque material. e should be carefully instructed to avoid coughg and swallowing whilst the injection is in gress and to make no attempt to phonate, but ould he, for any reason, wish the injection to be pped, *to* raise the hand, when the operator will move the instruments from his mouth and make y readjustments that may seem desirable.

The curved cannula attached to the special syringe passed over the epiglottis, the valve in front gently pressed, and the lipiodol allowed to flow between vocal cords. Flooding the larynx, which may ur if the injection is made too rapidly, should avoided. There is no special danger associated this, but the patient may become alarmed and peration interrupted.

hen the injection is completed the best results obtained if the patient is X rayed at once, both the erect and recumbent positions. Afterwards he ould not take any *food* or beverage for three four hours, in order to allow the effect of the æsthetic to pass off.

The actual injection can be made with the patient ther sitting up or semi-recumbent on the X ray able when, if a little care is exercised, there is no pecial tendency for the oil to flow into the œsophagus, nd it has the additional advantage that the patient ready for the X ray exposure at once, or can be olled to one side or the other, or the hips raised to nable the *oil* to flow in whatever direction may be esired. As there is no special inconvenience attaching to the operation and usually patients offer very ittle objection to repetition, it is probably better not o attempt to inject the whole of both lungs at one itting but to make a second injection later, injecting not more than 20 c.cm. the first time.

Severe cough and large amounts of sputum do not contra-indicate the procedure and give rise to no inconvenience, provided the tubes or cavities are emptied by posture, as already indicated. In one case a patient coughed up six ounces of sputum just after the commencement of anæsthetisation, notwithstanding which it was completed and the lipiodol injected without further trouble. No special discomfort was complained of, and the result was quite successful. In only three of the cases referred to in the Table was lipiodol found in the stomach in any appreciable quantity. This occurred before the technique had been fully worked out. No tendency to swallow has been noticed, and in no case has a patient complained of any special discomfort either during or as the result of the operation.

The following solution may be conveniently used in the atomiser: Solution adrenalin (1–1000), dr. 2; potassium sulphate (2 per cent.), dr. 2; cocaine hydrochloride (10 per cent.), dr. 4; (acid carbol., 0·5 *per cent., as solvent*).

For those who require a smaller compressed-air cylinder the British Oxygen Company make one containing ten cubic feet only, which takes the standard regulator valve fitting. An oxygen cylinder may also be used.

I am deeply indebted to Dr. G. S. Todd, the resident medical officer of the Brompton Hospital, who has largely helped to work out the steps of the technique, and without whose skill and assistance it might have been difficult or impossible to perfect the operative procedure detailed. I am further indebted to Mr. Spence, the chief dispenser, for the valuable assistance which he has given me.

I wish also to record my thanks to Messrs. Down Brothers for their care and skill in making the apparatus from my drawings and calculations, and to the British Oxygen Company for the trouble they have taken in adapting the regulator valve for the special purposes required.

SOME CASES OF "TRAUMATIC NEURASTHENIA."

By Millais Culpin, M.D. Lond., F.R.C.S. Eng.,

PROFESSOR OF MEDICAL INDUSTRIAL PSYCHOLOGY, LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE; LECTURER IN PSYCHONEUROSES AT THE LONDON HOSPITAL MEDICAL COLLEGE.

The original conception of traumatic neurasthenia was recalled by Sir Farquhar Buzzard seven years ago in an address to the Oxford Medical Society[1] when he spoke of the view that "an injury of any degree of severity and inflicted at any site may produce a physical condition of the nervous system, with characteristic signs, but without any morbid anatomy, to which the name traumatic neurasthenia is fairly applicable." He showed how legal judgments are based upon the belief that there exists such a disorder which, having a name, is part of the established order of things and in no need of further definition. It should, however, be regarded as an emotional state, an anxiety neurosis, dependent not on any physical disturbance caused by trauma, but on a number of psychological factors. The condition is not the result of an injury, but of the knowledge that an injury has been sustained, together with the ability to shift the responsibility for the injury and its effects on to other shoulders.

Yet difficulties would remain even if the truth should become recognised that a condition of ill-health and disablement can be the result of psychological influences alone. A decision that compensation could not be recovered for neurasthenia following an accident might be the subject of an outcry, though the contrary decision is a direct encouragement to the development and maintenance of that state. The legal problem, however, said Sir Farquhar Buzzard, is not for us to solve, though sooner or later it must be faced. It is our duty to prevent the development of the condition, and our weapons must not be merely the advice to take plenty of exercise in the fresh air, and a bottle of medicine repeated week after week, but a free expenditure of time devoted to fathoming the contents of the patient's mind, and an honest endeavour to re-establish a healthy mental outlook.

---

[1] The Lancet, 1923, ii., 1285.

With these views I am in almost complete agreement. I differ in so far as I think we must admit that an anxiety state can follow various kinds of shock in the absence of the compensation factor. In many cases that come to the stage of compensation the anxiety state occurs first, and is then neglected and allowed to develop, so that the unfortunate patient is given no alternative but to devote all his energies to the obtaining of compensation. The fears that make up so much of the symptoms of an anxiety state are not imaginary (whatever that may mean) but are to the sufferer as real as toothache. He sees in them a proof of damage to his nervous system (whatever that, too, may mean), and is compelled to cling to compensation as his only safeguard for the future. In cases that are treated early enough the man may eagerly grasp at a correct presentation of his state, seeing a gleam of hope hitherto absent through the belief in some mysterious injury to his nerves.

Thirteen years ago, in an article on the Early Stage of Hysteria,[2] I maintained that no example of hysteria had ever been accurately described ab initio, for the reason that anyone capable of recognising and describing it would not allow it to develop. Although the subject is not so simple as I then believed, yet my observations point to a similar deduction about traumatic neurasthenia. Even the medical men acting for accident insurance companies take for granted the old conception or, as so often happens in the minor psychoses generally, accept an initial diagnosis of some physical lesion that later gives way to the doubtfully more correct diagnosis.

This view of the preventable nature of hysteria and traumatic neurasthenia is perhaps not easily accepted by those who take the psycho-analytical view of the minor psychoses, which involves more subtle and complicated mechanisms. Experience compels me, however, to accept both views, and a sufficiently wide survey shows no incompatibility. My work for the Industrial Health Research Board[3] satisfied me that in the working population there is a reservoir of people who, suffering from symptoms that interfere only slightly with happiness and efficiency, are nevertheless ready to fall victims to any pseudo-neurological disorder that may offer itself. That disorder, though called into being by immediate causes, is intimately linked with the previous condition, and, if left to develop, becomes consolidated with it. Thus a traumatic neurasthenia is identical in its general structure with those other disorders for which psycho-analytical principles offer a pathology and a means of treatment; it differs from them in the influence of compensation in conjunction with the anxiety patient's fears about his economic future. An accident, some more or less severe anxiety symptoms, a false pathology accepted by doctors, lawyers, and the public, a lively apprehension about the future, together with compensation in place of understanding and rational treatment, make up a combination that has brought many a decent citizen to disaster.

Compensation Cases.

Last year I had the opportunity of examining a batch of miners receiving compensation for traumatic neurasthenia. They were examined at the rate of two per hour, and a physical examination was necessary, though in some cases it was only a placebo. The history of each case was before me, and the following notes will show what a medley is to be found under that unfortunate diagnosis and how each case presents a different problem.

CASE 1.—Aged 47. Married; two children, aged 6 and 11. Injury to head by fall of stone, July 25th, 1916. Suffered concussion. Returned to work August 24th, 1916. Resumed incapacity Oct. 9th, 1918. Doctor reported that he was suffering from bruised head and giddiness. Got work on the surface, and on April 11th, 1919, doctor reported: "He is in a very nervous condition, hands tremulous and pulse very rapid; probably neurasthenia following injury." In 1926 the matter was referred to the Miners' Welfare Committee, who stated they were not in a position to deal with cases of neurasthenia. Report on Nov. 15th, 19 states: "Traumatic neurasthenia still very bad, very shaky, couldn't do anything."

The man showed coarse tremors. Described feeling being stared at which prevented his going about. H fears of traffic and described hallucinations of traffic go "contrariwise." There were puckered scars on the che and a tumour of the lower jaw, which was ankylosed. F three years he had "lived by suction."

The presence of the tumour—probably acti mycotic—overshadowed the nervous condition, whi was a typical anxiety state.

CASE 2.—Aged 34. Two children, 10 and 3. injured by a shot on June 25th. The left eye had to removed. Slight corneal scar on right eye. Face b disfigured. Half right ear missing. On April 11th, 1 doctor reported that the man had to wear blue glasses would never be any better. On June 26th, 1927, a re said: "The most important effects of the explosion h been on the nervous system, and on the eyes. The e on both have been severe. He shows all the signs profound neurasthenia. The intolerance of light is d this cause, not to the eye injury. A little improve in the condition of his nerves would enable him to disp with the very dark glasses which he wears; they a themselves a depressing agent . . . . He needs to be out of the rut in which he is at present. Otherwise he make no progress."

The man appeared before me accompanied by his and wearing the darkest possible glasses. He showed yielding grip that I regard as a hysterical stigma. plained of headache and being kept awake by pain. " panel doctor says it's the nerve at the back. It's the nerve. I go trembly when I am away from anyone. least bit of trouble upsets me. I never go out. U to sit and nurse my eyes. I've come out of bed to see I don't know where there's another man who's stood I've stood." When I suggested that he should try t without the glasses his wife said, "If he does that have to go to bed altogether."

A hopeless case of hysteria with anxiety. attribution of the hysterical photophobia to "profo neurasthenia" is, I am afraid, quite orthodox, the reference to the condition of his nerves.

CASE 3.—Aged 36. Married; three children. July 11th, 1929, was found to be suffering from s caused by witnessing a fatal accident to a fellow work Doctor reported that his pulse was very rapid and h very trembling. On March 15th, 1930, doctor rep that the man was suffering from shock and the cond remained unchanged.

The man complained to me of pains in his head. H bad day last week when he felt down and out. Wo about money; is on light work. When asked to tell ab the accident he refused. "I want to forget that. I to forget it." Asked about dreams he said: "It's alw one dream" (i.e., the accident). "My wife says I n jump out of bed. I have to keep to the shop side for f of the traffic rushing at me. I see things in the dark. must sleep with a light. It's always the one thing." this point I suggested that perhaps if he talked to some about the accident it might help him. He said: "I always been on the hard side. I don't believe in telli people those things." Here he cried and admitted that often cried when alone. For three weeks he had stuck down pit, but fear made him sweat so much that his cloth "wanted to go through the mangle." When at work felt all the time that the roof would come in again. I fina prevailed upon him to tell me about the accident. A f of roof had buried one man, and whilst P. M. was directi rescue work another fall buried one of his mates. tried to dig this man out; he felt him with his hands the dark and could tell by the feel that he was dead. (told this under obvious emotional restraint.)

The picture found on proper investigation is wonderful contrast to the meagre account of h ondition first given, but he would have told me othing about his real symptoms if I had not pressed im. The case is clear-cut, and any psychopathoogist will agree that with informed treatment the rospect of recovery is excellent. The man was a tout-hearted fellow, and I feel strongly about the ct that, short of bringing him to London, there was o means of giving him that psychological treatment hich would restore his peace of mind and efficiency. e must all accept the responsibility for our neglect f modern teaching and for clinging to the pernicious ord "neurasthenia" and all that it involves. In is case a certain amount of technique would be ecessary in the treatment. I refer to the process of reaction, which is successful in recent cases like is; the effort to forget would perhaps be approved some of my readers, but I can assure them that is a disastrous way of handling such an experience. the circumstances I did not venture there and n to use the method described in Case 11.

---

[3] The Nervous Temperament. I.H.R.B. Report No. 61. H.M. Stationery Office.

CASE 4.—Aged 33. Married; five children. Suffered electric shock on June 8th, 1928. On June 30th doctor orted: "*Effect of electric shock; does not look well;* se rapid, says he is much better." He returned to work, on Sept. 10th he broke down and had to be *carried out* the pit. There was some difference of opinion as to ether his condition could be attributed to the shock. was examined on Oct. 17th by a doctor who elicited ety *symptoms, discussed the alternative* of malingering, reported that, "This man is suffering from neurasthenia, direct result of the electric shock. In my *opinion,* ough there may be some exaggeration, he is quite uine *in* his complaints. I think a change at Skegness ld brace him up." On Jan. 25th, 1930, a doctor reported: "He is anæmic and neurasthenic; could do a *lot* of k on surface."

t the interview his palms were sweaty and his grip led to yield; he talked freely about aches and pains his heart (*these patients often withhold the anxiety* ptoms until they recognise that these will be accepted enuine). Then he admitted that he got scared and ated. "I fancy things and dream awful; wake in a . Can't sleep without a light. (Asked what would n if his wife took it away.) "I'd soon move down-. Can't stand the kiddies talking. If you came ed me you'd set me off. I always dread the traffic; akes me go all of a sweat. It's no good me going down am. A surface job might take a lot of this out of me." said he had paid 8 guineas for massage in the hope of cure.

This man is in a severe anxiety state. Proper ndling of the case from the start might have vented this deterioration of a decent workman, treatment would now be a lengthy matter and outcome doubtful.

CASE 5.—Aged 69. On April 29th, 1927, a fall injured his ad. He was trephined for a fracture just above the right stoid, where there is a deep depression bigger than a f-crown. Doctor's report on Nov. 22nd, 1929, said: "Skull fractured; neurasthenic; looks well; pulse al; will never improve." Complains that he is deaf that his head is all of a rumble. Gets shaky when nding. Jumps at a miss-fire. Can travel in a motor-bus. es to the pictures; reads books and newspapers. "Might well be dead if I didn't have a bit of fun. I've smoked ce I was 7 and it hasn't stopped my growth." He has a ar of losing his balance when he comes downstairs.

In view of this man's age and the severity of his jury, which affected the internal auditory apparatus, is mental outlook is very good and the diagnosis neurasthenia is redundant under any hypothesis.

CASE 6.—Aged 40. Married; three children. Sustained jury to his back by a fall of bind on Oct. 17th, 1925. On arch 6th, 1926, doctor reported "Concussion of spine; ray report is 'fracture transverse process vertebra.' is back is doing well, but general nervous condition bad; think a convalescent home at the sea is indicated." On arch 31st, 1926, doctor reported: "The fracture united ell and there was no organic lesion, but he was badly haken and his nerves were upset. He had tachycardia or a time. For the last six months his pulse has been ormal." Notice of reduction in the compensation was erved, but the doctor reported that the reduction had so pset the man that at the moment the doctor considered he was unfit for work. He was therefore reinstated on full compensation. A note on Sept. 21st, 1929, says: "The colliery are unable to start him at the pit, and the man is trying to obtain outside work."

At the interview he complained that he was not feeling well. "My back gives way when I walk. I burst into a sweat if I slip. I get pain in the head on *bending.* The strength goes out of my legs. I can't stand the noise of picture shows. I get a pain in the privates." I asked: "Do you feel anything else *the matter?*" and pressed the question without eliciting further *symptoms.* *His wife* was present and I asked her: "How does he sleep?" She told of how she wakes him up because he makes all *sorts* of noises. The man, now asked about these noises, said: "I dream of the accident and the *wife* wakes me up," then admitted that he was restless and afraid in a room by himself (claustrophobia). Is frightened in the dark. "*If* I meet a cat or dog in the night I burst out all of a sweat. Nervous in a bus. On the pavement I keep thinking the buses are running into me." Asked whether he could go down pit if his back were all right he said, shamefacedly but sincerely, "It's not a nice place to go when you are frightened." He had *given reactions* to examination of his back that might be either hysterical or malingering.

This man had never told about his anxiety symptoms and would have withheld them from me if he had not realised that I was taking them seriously. It is possible that his back symptoms were deliberately feigned, but even if that were so I should not call him a malingerer. In the absence of recognition of his real symptoms he was compelled to develop hysterical symptoms or malinger them. I amused myself by asking why he had not told other doctors about his fears; he made no verbal answer, but I translated the look he gave as "I thought you had more sense than to ask me that."

A recognition of his true disability, even in the absence of treatment, might have saved four years being wasted in the expectation of a claustrophobe with a severe fear of the dark ever going to work again down the pit. In miners' nystagmus, which is a variant of traumatic neurasthenia, I believe that the night-blindness is a hysterical conversion of fear of the dark.

CASE 7.—Aged 32. Married; two children. On April 6th, 1927, was pinned between a fall of stone and a tram, was taken by ambulance to hospital and diagnosed fractured pelvis. On Oct. 24th doctor reported: "He walks fairly well on the level; there does not appear to be any tilting." He went back to work on Dec. 30th, 1929, but ceased the following day. On Jan. 6th, 1930, a report read: "He has a fractured pelvis, but a sitting down job 50 yards from the pit bottom has been found, and I think he is quite able to do it." On March 13th, 1930, it was stated: "There is a good deal of neurasthenia about this case." The man said he had never been free of pain since the accident. Couldn't bend. Sometimes has trouble with his water. Sweats between the legs. On examination he claimed hyperæsthesia to light pin-prick in the left lumbar and gluteal area, with pain to deep pressure. I flexed the right leg and said: "Of course you can bend this all right," and when I attempted to flex the left leg he resisted violently with loud groans. He stoutly denied any nervous symptoms. His wife likewise was annoyed that I should suspect them. Asked if he made noises in his sleep she said snappishly: "I don't stay awake to listen." I asked him if he walked "on the shop side of the pavement." He accepted that suggestion and explained that his walking was so insecure that he kept away from the kerb for safety.

I could suggest whatever physical symptoms I fancied, and have them accepted, but in the absence of nervous symptoms he regarded my search for them as an attempt to trap him. This mode of reaction is typical, and meets the common innuendo that those nervous symptoms found by the psychopathologist are suggested by him. I decided that the man's symptoms were a wilful attempt to deceive me. This case should be compared with the preceding one, with which it was identical on a superficial examination.

CASE 8.—Aged 46. Married, four children. On Dec. 24th, 1915, a piece of bind fell on his shoulder. He was taken home in an ambulance. On Jan. 7th, 1916, doctor reported: "Severe bruise over lower dorsal and upper lumbar spines; sphincters were affected for two days." Work and incapacity alternated till June 15th, 1919, when doctor reported: "Slight lateral curvature of spine and marked tenderness over spinal column." On Jan. 28th, 1921: "There is marked apparent tenderness over the spine and slight curvature. Movement of the back is fairly good. He complains bitterly of local pain that keeps him awake. I am inclined to think the case is more one of traumatic neurasthenia than of real organic injury." On March 6th, 1929: "There is no improvement in his condition. He states that he is 42 but looks 55. Complains of headaches and pain in the back. He can only control urine by passing it frequently. He is suffering from traumatic neurasthenia and some light occupation would tend to improve his condition."

The man's appearance was worse than the above description indicates. Haggard, spineless, wasted, with clammy skin, he was a picture of despair. Said he had been crushed all over his body. His legs go dead and his head aches. He dreams of the accident still and wakes frightened (statement volunteered). His wife broke in with: "Yes, he frightens me. If he goes to sleep he's always in trouble." Is not afraid in a bus, and denies specific fears. I tried to put it to him that he had given up all hope, and let himself go downhill, but that the effect of the injury must have worn off by now, and he ought to try to get some pleasure out of life. My reward came from the wife, who said, as a farewell to me: "He'll be in bed a month after this."

CASE 9.—Aged 47. Married, four grown-up children Was caught in a fall of coal on July 27th, 1923. On August 13th report said: "Crushed and bruised back and abdomen; he says that he vomited in the pit." On Oct. 22nd: "Alleged abdominal pain; his symptoms now are chiefly nervous; heart action very rapid." On Jan. 14th, 1924: "Valvular disease of the heart; pulse 130; he says he feels better." In June, 1926, doctor reported: "I attribute the rapidity and weakness of the heart to damage of the nerves of the heart caused by a severe crushing accident. The rapid action of the heart will tend to exhaust the heart and shorten life. I could discover no other cause likely to affect the heart in this manner, and with such a clear history available it is fair to attribute the man's condition to the accident." The man complained of his stomach and heart. "I'm beat to the wide. I got crushed and have not been right since. I go all of a jake." In answer to questions: "I always creep to the wall. It seems to be dread all the while." Has a fear of thunder—had it as a boy. Never went to pictures or to football. Wakes up frightened from bad dreams. Has given up smoking because of the effect on the heart. Pulse was 140 when resting; 160 after exercise; 132 two minutes later.

This man presented that syndrome, so common during the war called "disordered action of the heart" and invariably associated with its causative anxiety. He seemed to promise results from treatment and was sent to a physician familiar with this type of case, who wrote, however, warning me that he could rarely get good results in long-standing compensation cases and did not anticipate much benefit in this one.

CASE 10.—Aged 51. Married; two grown-up children. He alleged that on August 2nd, 1923, he got his head between a tub and a prop and bruised it. There is no evidence in the history that this happened or was of any severity if it did happen. He walked home, had supper, and told his wife he would have a smoke before going to bed. He seems to have gone away in a fugue state and was sent home by the police, who identified him by the tally attached to his pit clothes. His behaviour since has been very troublesome and erratic. Diagnoses have been offered of fright neurosis, melancholia, epileptic mania, and, of course, traumatic neurasthenia.

I found him a sensible man and he gave a history of various troubles of behaviour. I did not venture to add yet another diagnosis to the list, though I fear he will end up with a major psychosis. His initial fugue would probably have given up its secret to modern psychological technique, but it is not generally recognised that such technique is applicable to these cases.

The next case is given as a contrast to Case 3, and shows how a timely application of modern technique can at a single sitting arrest the process of deterioration. The diagnosis of neurasthenia was never made because the patient had the fortune to come under the charge of a woman medical officer, attached to her factory, who had discarded the diagnosis and accepted the psychological view. The following is the woman doctor's account of the case:—

CASE 11.—In the autumn of 1928, friends of the patient came to me to ask if I could do something for her as they were afraid she would do herself some harm; said they could not persuade her to be with them, that she persisted in keeping by herself, and stayed out all night walking by the Embankment. She would not eat and her work was suffering. These symptoms had arisen after the suicide of her father in July, 1928.

The patient, a forewoman aged 27, came to me ve pale and thin; reticent to the point of sullenness. Wo not answer when asked to tell what was the matter, after a few general questions said that she had lost appetite and could not sleep and was "terribly worri She was living by herself, as she could not go home to mother, who was queer and did not understand her had made her father do what he did. Here she bec emotional and cried bitterly. I made her lie down i quiet and darkened room and asked her to tell me what was thinking about. For a long time she wouldn't sp and then she said: "I can see it, the horrible thing. black and ugly . . . it's awful . . . . I can't, I can She buried her head in her arms and pressed her hands her eyes. I asked her to tell me what she saw, and she up suddenly and screamed and then with eyes wide staring she described how a policeman had taken he a place and she saw her father with a terrible look. him lying in a black open coffin. She cried for some and then became quieter and seemed to doze. Later friends came and took her home; she appeared pl to go with them. I saw her a few days later and she much quieter but very silent; said she was sleeping b I inquired from time to time how she was, and both she her friends said there was a great improvement, but she was still apt to have fits of depression and was difficult.

In February, 1931, I had a long talk with her fo purpose of this history. She had gained weight, pleased to talk, and answered questions helpfully, but still a bit shy. She gave an account of family strife c by a mother whose domineering qualities seemed pa logical, and whom she still blamed for the father's sui She now felt that her father's death was not a dre thing, that he was at peace, and there was some sor bond between them. She could think of her visit to mortuary but at night the shadows on the wall seem to like the black coffin. She made the best of her w though she did not like it; her hobbies are walking, te and music, with reading. Asked if she liked men replied: "Not young men; they cannot talk to one like older men. . . . The only man I ever loved was Dad She is grateful to and fond of her women friends, who good to her and put up with her when she was ill and diffic

This woman is still hampered by a parental fixati but a timely abreaction had produced a therapeu effect unattainable by the prescription of bromi and advice to "forget all about it." I have doubt but that similar treatment would have led to similar result in Case 3. The next case illustra a different method of handling a patient.

CASE 12.—Aged 34. Married; three young children. A skilled worker in compressed-air jobs. In June, 1930, an accident happened to the air lock. There was a rush for safety and this man was the last to get out. He was speechless, his stomach and neck were "drawn," and he was choking. This he attributed to the sudden change of pressure—*i.e.*, to caisson disease. Now he complains of severe pains; goes giddy and staggers; has been picked up in the street and taken into hospital; describes having injections and inhalations (probably amyl nitrite); has been in four hospitals and his wife has been warned to prepare for the worst; gives accounts of various diagnoses. Has a severe fear of the dark. Never goes out alone. Is afraid to travel on trains. He is receiving compensation of 3s. per week, but does not know under what diagnosis. In January last he sought treatment at Richmond Hospital where Dr. Geoghegan recognised the nature of his disorder and, judging him to be a decent man desirous of cure, asked me to see him. I elicited the history given above and confined my physical examination to testing his grip, which gave a hysterical reaction.

I gave him a straight talk, telling him that his symptoms had no relation to caisson disease, that they were the result of a severe fright which had upset his feelings and emotions, but that the most powerful microscope would find nothing wrong with his brain or nerves. It was for him to make the effort to recovery, but if he did not accept my view and make that effort he would go downhill and become a useless wreck. Then I demonstrated that his yielding grip was really under his control and that if he put his energy into it I could not open his closed fist. He and his wife took this onslaught so gratefully that I decided to help him to get treatment at the Tavistock-square Clinic and arranged to see him again at the end of a week. He came then, looking a different man, and said: "I've taken my medicine and am going to get well. I've come here alone, and that is the first time I have been out by myself for six months."

This case is not yet complete, but I have little doubt about the result. Clinically it is interesting n account of the unfavourable prognosis given to he wife—a story which I have no reason to disbelieve. once described a case in which the patient had been ut on the "dangerously ill" list and treated with owerful heart stimulants for a condition which a olleague was able to reproduce under hypnosis, his own embarrassment and fright. I saw the atient myself in his attacks and he looked moribund, et the whole trouble disappeared after the abreaction a suppressed emotional experience.[4] In Case 12 e attacks are probably reproductions of the emotional perience at the time of the original accident and ould be curable by abreaction, though the man's anged outlook may suffice to render that necessary.

Turning back to Cases 2, 4, 6, 8, and 9 we may ask hether those men had been given a fair chance recovery and whether we are justified in the perficial view that they cling to their symptoms fear of losing compensation. The situation s been thrust upon them as it is still being thrust on numberless other victims of an out-of-date ytho-pathology.

A CASE OF THROMBOCYTOPENIC PURPURA.

BY A. M. KENNEDY, M.D. GLASG., M.R.C.P. LOND.,
DIRECTOR OF THE MEDICAL UNIT, WELSH NATIONAL SCHOOL OF MEDICINE, CARDIFF; AND PROFESSOR OF MEDICINE IN THE UNIVERSITY OF WALES.

A YOUNG woman at the age of 18 began to notice that she bruised very easily and often without any obvious cause. Previously she had always been healthy—apart from measles, scarlet fever, and an attack of shingles in childhood—and there was no history of any similar complaint or other forms of bleeding in any of the other members of the family. Paying no attention to these bruises, she was not incapacitated in any way until a couple of years later, when she had a severe menorrhagia lasting about three weeks. Before this, menstruation had always been normal, but afterwards, while recurring regularly at monthly intervals, it would last ten days and the loss would be excessive.

Her doctor gave her two injections of Hæmoplastin and a short course of calcium lactate by the mouth, but these had no effect and she became, in consequence, pale and anæmic, suffered from faintness, and had some œdema of the ankles after standing. Gynæcological treatment was next undertaken. The cervix uteri was dilated and the uterus curetted, and seven weeks later radium was inserted into the uterine cavity for 24 hours. Her blood count at this time was:—

Red cells	2,900,000 per c.mm.
White cells	11,000 " "
Hb (hæmoglobin)	32 per cent.
C.I. (colour-index)	0·5
Plat. (platelets)	96,000 per c.mm.
Retic. (reticulocytes)	Not counted.

Next she took cooked liver for about seven weeks. She tried ¼ lb. daily but did not like it, and only managed to take about half this daily quantity. Her condition was in no way alleviated, and, six weeks after stopping the liver, she was admitted to hospital under my care. During these six weeks she had had two severe attacks of menorrhagia, lasting 12 and 11 days respectively, and a third, less severe, lasting seven days, and one attack of nose-bleeding.

She was now 21 years of age, 8 st. 4lb. in weight, well nourished, but very anæmic. Examination revealed large subcutaneous bruises on the limbs, and a few purpuric spots on the chest and above the left ankle. The spleen measured 3½ in. on percussion, the liver was not enlarged, there were no enlarged glands, and the heart was within normal limits. Two teeth were rather carious, but no other features of note were to be made out except on examination of the blood. Blood examination at this time (Feb. 28th, 1929) showed:—

Red cells ..	2,000,000	Polymorph. ..	69 %
White cells ..	12,200	Eosin.	1 %
Plat.	15,000	Lymph.	22 %
Retic. ..	0	Large mono. ..	7 %
Hb	25 %	Mast	1 %
C.I.	0·56		

Red cells poorly stained. Average diameter less than normal; no nucleated reds or poikilocytes present.

The case was considered to be one of chronic thrombocytopenic purpura and, as the patient was averse from operation, the opportunity was taken to observe the effects of various remedies on the condition, and especially on the blood-platelets. With this object in view, the blood was examined regularly at weekly or bi-weekly intervals, while the patient was in hospital and afterwards at longer intervals. It was obvious that such liver treatment as she had had already over a period of seven weeks had not increased the number of platelets in her blood stream or alleviated her condition generally.

EFFECT OF VARIOUS REMEDIES.

She was tried first (Feb. 28th) on calcium lactate, grs. 15 t.i.d. orally, and at the end of one week it was found that the red cells had increased to 3,600,000 per c.mm. and the hæmoglobin to 30 per cent., but the white cells had fallen to 6200 per c.mm., and the platelets were unchanged (15,200 per c.mm.); subcutaneous bruises continued to appear spontaneously.

The calcium lactate was continued but cod-liver oil emulsion (2 drachms twice daily) was then given also, and ultra-violet light administered twice weekly. It was thought that the vitamin D in the cod-liver oil might assist the calcium metabolism, and that the ultra-violet light, as well as the vitamin A in the oil, might produce an increase in the blood platelets. In this connexion it may be recalled that Cramer, Drew, and Mottram[1] found in rats that the blood-platelets were reduced in vitamin A deficiency, and that the addition of the missing vitamin A to the diet was followed by a rapid rise in the number of platelets, provided that the animal had not been allowed to suffer too long and too severely from the deficiency. In further experiments these authors[2] found that exposure to ultra-violet light increased the number of platelets in rats whose platelet count had been reduced through being born and kept in darkness on a diet of low vitamin content.

---

[4] Psychoneuroses of Peace and War. Cambridge, 1920, p. 112.

At the end of a week's treatment with ultra-violet light, cod-liver oil and calcium lactate, the patient's red cells had increased to 4,100,000 per c.mm., but the hæmoglobin had remained at 30 per cent., the white cells at 6000 per c.mm., and the platelets at 15,000 per c.mm., and subcutaneous bruises continued to appear spontaneously as before, although her general condition seemed better.

Parathyroid tablets (gr. 1/10th = gr. 1 fresh gland) orally, twice a day, were then added to the treatment, for any possible effect they might have in assisting the distribution of calcium in the body. This combined treatment—calcium lactate grs. 15, t.i.d.; parathyroid tablets gr. 1/10th, b.d.; cod-liver oil emulsion 2 drachms, b.d., and ultra-violet light twice weekly—was kept up for another three weeks, but no further improvement was produced in the blood. At the end of this time (March 30th) the blood count was :—

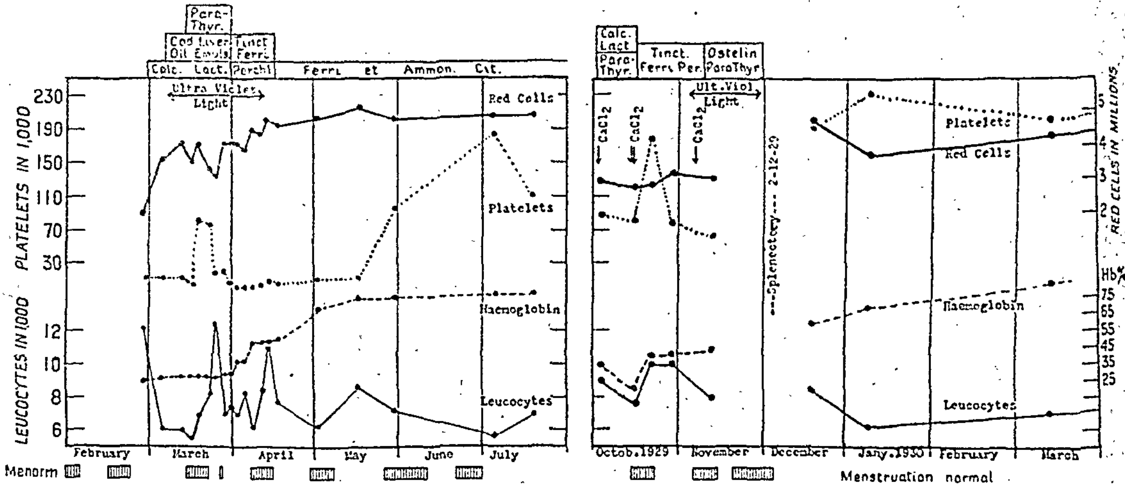

Chart showing effect of various forms of treatment, including splenectomy on Dec. 2nd, 1929.

Red cells, 4,180,000; white cells, 7500; platelets, 9200; Hb, 30 per cent.; C.I., 0·37.

A week after the above combined treatment was started the patient had a distinct relapse. Menstruation set in and persisted for seven days, fresh crops of purpuric spots and more bruises appeared, and the patient's general condition seemed much worse. This relapse, however, was associated with an intercurrent rise in the platelet count. At the onset the platelets shot up to 85,000 per c.mm., but they fell again to 25,000 per c.mm. within nine days and to 9200 per c.mm. three days later.

The cod-liver oil, parathyroid, and calcium lactate were now stopped, but the ultra-violet light was continued twice weekly and tinct. ferri perchlor., ℳ xv., was given orally every six hours for a further two weeks. The hæmoglobin now began to increase in amount and the red cell count improved still more, but the platelets were unaffected. The patient's general condition also improved and, although never absent entirely, new bruises occurred less frequently. Menstruation recurred for six days, the interval from the preceding flow being just over three weeks. At the end of the fortnight's treatment with tinct. ferri perchlor. and ultra-violet light the blood count was as follows :—

Red cells, 4,870,000; white cells, 11,000; platelets, 12,000; Hb, 52 per cent.; C.I., 0·5.

The patient had now had five and a half weeks' treatment with ultra-violet light and no increase in the blood-platelets had occurred. During the first week of the treatment the patient also received orally calcium lactate and cod-liver oil and, notwithstanding the vitamin A of the latter, only the red cells were affected—rising from 3,600,000 per c.mm. to 4,100,000 per c.mm. During the succeeding three weeks, when parathyroid was also administered orally, no further change in the blood took place. Then, at the end of this period, on substituting tinct. ferri perchlor. for the cod-liver oil, calcium and parathyroid, for the first time the hæmoglobin began to rise. It increased from 30 per cent. to 52 per cent. in less than a fortnight and the red cell count improved still further.

It was obvious that the ultra-violet light had produced an increase in the red cell count only, and that iron was needed for the formation of hæmoglobin. The ultra-violet light therapy and tinct. ferri perchlor. were now stopped and the patient was given ferri et ammon. cit. grs. 10, t.i.d., for the succeeding three and a half months. The hæmoglobin increased steadily to 76 per cent., the red cell count remained about normal, but the platelets were practically unaffected until the occurrence of a prolonged (15 days) and severe menorrhagia six weeks after starting the citrate of iron and ammonia. They then shot up to 100,000 per c.mm. Ten days after the cessation of this menorrhagia another attack occurred for about seven days and the platelets then shot up to 185,000 per c.mm., but fell again, two weeks later, to 110,000 per c.mm. Spontaneous subcutaneous bruises had continued to appear from time to time—and occasionally purpuric spots—but nevertheless the patient's general condition was now very good indeed and she left the hospital (see Figure). At the end of her course of treatment with ferri et ammon. cit. the blood count was as follows :—

Red cells, 4,900,000; white cells, 7000; platele 110,000; Hb, 76 per cent.; C.I., 0·76.

FURTHER PROGRESS.

The patient remained in fairly good health for th next seven weeks, and then she had another severe menorrhagia, and felt so ill and faint that she had to go to bed. A fortnight later she was transferred to hospital again under my care. Blood examination at this time (Oct. 3rd) showed :—

Red cells ..	3,000,000	Polymorph. ..	75 %
White cells ..	9,000	Eosin.	1 %
Plat.	92,000	Lymph.	18 %
Hb	35 %	Large mono. ..	6 %
C.I.	0·53		

Red cells poorly stained—many showing marked central pallor. Coagulation time practically normal (Dale and Laidlaw's method).

An intramuscular injection of calcium chloride was administered at once and calcium lactate, grs. 15, t.i.d., and parathyroid tablets, grs. 1/10th, b.d., were given orally for ten days, but the red cells, white cells, hæmoglobin, and platelets decreased further and the patient got much worse. She became very weak and ill, pallor increased, and severe menorrhagia again set in at the end of a week (Oct. 13th). On the day following the onset of the bleeding the blood count was :—

Red cells ..	2,800,000	Polymorph. ..	64 %
White cells ..	7,800	Eosin.	1 %
Plat.	85,000	Lymph.	26 %
Hb	20 %	Large mono. ..	8 %
C.I.	0·32	Mast	1 %

Coagulation time about a half longer than normal.

On this day she was given two intramuscular injections of calcium chloride and put on tinct. ferri perchlor. grs. 15, six-hourly. A week later the vaginal hæmorrhage stopped and the patient had an attack of acute abdominal pain, lasting throughout one night, and aching pain in both legs, especially behind the knees, lasting about a week. On the day following the attack of acute abdominal pain and cessation of the menorrhagia, a blood examination showed that the platelets had shot up to 180,000 per c.mm., but a week later they had fallen to 78,000 per c.mm. On both occasions, however, the coagulation time was practically normal. The two weeks' treatment with tinct. ferri perchlor. alone produced a rise in the hæmoglobin of 20 per cent. (from 20 per cent. to 40 per cent.), but the red cell count was increased only by 400,000 per c.mm. (from 2,800,000 to 3,200,000 per c.mm.). *Ultra-violet light therapy* was then given twice a week and the tinct. ferri perchlor. continued. Two days later (Nov. 6th) menorrhagia again set in and, in spite of an intramuscular injection of calcium chloride, persisted for six and a half days. In the middle of this period of menorrhagia the tinct. ferri perchlor. was stopped and vitamin D, in the form of Ostelin and parathyroid t.i.d., substituted.

The combination of ultra-violet light and ostelin with parathyroid was continued for a fortnight, and at the end of that period the red cells had risen to 3,900,000 per c.mm. and the hæmoglobin to 44 per cent., but the platelets had fallen to 62,000 per c.mm. The coagulation time was normal. The patient's general condition was no better, menorrhagia recurred (Nov. 20th) at an interval of seven and a half days from the previous attack, headache and abdominal pain were troublesome, and fresh petechial spots appeared. She had never been completely free from spontaneous subcutaneous bruises, and at last she agreed to have splenectomy.

SPLENECTOMY.

The operation was performed on Dec. 2nd by my colleague, Prof. A. W. Sheen, and two days later the vaginal hæmorrhage, which had persisted for 14 days, ceased, and recovery from the operation was uneventful. The next examination of the blood was done 16 days after the removal of the spleen (Dec. 18th), and revealed the following :—

Red cells ..	4,630,000	Polymorph. ..	70 %
White cells ..	8,600	Eosin.	1 %
Plat.	192,000	Lymph.	18 %
Hb	60 %	Large mono. ..	10 %
C.I.	0·6	Mast	1 %

Red cells mostly of normal size and shape with fairly good colour. Coagulation time normal.

Three weeks later (Jan. 7th, 1930) the blood examination showed :—

Red cells, 3,500,000 ; white cells, 6200 ; platelets, 32,000 ; Hb, 70 per cent. ; C.I., 0·9. Red cells well [illegible]ned and normal in size and shape. Coagulation time [illegible]mal.

Two months after this (March 12th, 1930) the blood count was :—

Red cells, 4,270,000 ; white cells, 7100 ; platelets, 206,400 ; Hb, 81 per cent. ; C.I., 0·88. Red cells well stained and mostly normal in size and shape.

The patient continued to make satisfactory and uninterrupted progress after the splenectomy. Menstruation became normal, the recurrence of subcutaneous bruises and purpuric spots ceased, and the skin and mucous membranes acquired a good healthy colour. She had three teeth extracted a month after the operation, and there was no excessive bleeding. Five months after the splenectomy (May 1st) the blood count was :—

Red cells, 4,460,000 ; white cells, 7600 ; platelets, 210,000 ; Hb, 90 per cent. ; C.I., 0·9.

The patient was last seen about 17 months after the splenectomy and was very well indeed. There had been no recurrence of any symptoms whatsoever, and menstruation had remained normal (see Figure). The blood count on this date was :—

Red cells, 4,660,000 ; white cells, 8200 ; platelets, 18,000 ; Hb, 96 per cent. ; C.I., 0·96.

SUMMARY.

(1) A case of chronic thrombocytopenic purpura is recorded in which menorrhagia was a special symptom. (2) Ultra-violet light therapy produced no effect on the blood-platelets even when associated with the internal administration of vitamins A and D, in the form of cod-liver oil, and of calcium and parathyroid. (3) The red cell count was increased by ultra-violet light therapy, but no increase in the hæmoglobin content of the blood was produced until the internal administration of iron was begun. (4) Calcium intramuscularly and orally had no effect on the blood-platelets. (5) The disease persisted in spite of all the above forms of treatment, and the administration of liver did not affect it. (6) Splenectomy relieved all the symptoms and cured the disease at once, the blood-platelets rising quickly to, and persisting about, 200,000 per c.mm., and the red cells and hæmoglobin reached normal a little later. (7) Seventeen months after the splenectomy the patient was very well, the blood-platelets were 180,000 per c.mm., and the red cells, white cells, and hæmoglobin had remained normal.

CLINICAL AND LABORATORY NOTES

INTRALIGAMENTARY ECTOPIC PREGNANCY.

By H. R. McLennan, M.B., Ch.B. Glasg.,
OBSTETRIC REGISTRAR, GLASGOW ROYAL MATERNITY AND WOMEN'S HOSPITAL.

Three somewhat unusual cases of intraligamentary ectopic pregnancy have recently been treated at the Glasgow Royal Maternity and Women's Hospital. They are worthy of note in so far as they presented some similar and atypical clinical features.

Mrs. A., aged 40, para-5, last pregnancy seven years' previously, was admitted as a case of threatened abortion with a history of slight vaginal hæmorrhage of ten days' duration. Her last menstrual period had been six weeks previously. There had been some degree of menorrhagia before her missed period. Apart from vaginal hæmorrhage she had no other complaint and felt comparatively well. Bimanual examination revealed a retroposed uterus of normal size with a stony mass in the right and anterior fornix. There was no tenderness on examination. A diagnosis of fibromyoma of uterus complicating pregnancy was made and the patient was kept in bed for six weeks. During this time she remained well, but as vaginal hæmorrhage persisted and abortion appeared inevitable, laparotomy for myomectomy or hysterectomy was decided upon. At the operation a right-sided intraligamentary ectopic pregnancy was found and removed along with the tube. The uterus was healthy and lying twisted behind the mass.

Mrs. B., aged 38, para-2, last pregnancy ten years' previously, was admitted as a possibly incomplete abortion. She gave no clear history of having missed a period but complained of irregular hæmorrhage of two months' duration. Apart from vaginal hæmorrhage she had no complaint. Bimanual examination revealed a retroverted uterus of normal size with a hard mass in the right and anterior fornix indefinable from the uterus. No tenderness was elicited. A provisional diagnosis of fibromyoma of uterus or parovarian cyst was made and laparotomy was performed. Again an intraligamentary ectopic pregnancy was found separating the layers of the broad ligament and encroaching on the utero-vesical space, commencing to strip the peritoneum from the bladder.

In these cases the noteworthy features were the entire absence of pain. In neither case was sickness, nausea, or occasional faintness a complaint. No tenderness was elicited upon vaginal examination. The mass was much harder in consistence than might be expected, and apart from vaginal hæmorrhage both patients were healthy and comfortable. The pathological examination of the first specimen showed it to have undergone a mole degeneration. In the second case the sac was intact and complete with fœtus in situ and chorionic villi were embedded in the broad ligament.

The third case was something of a rarity—a patient with an advanced intraligamentary ectopic pregnancy being delivered by operation of a well-developed child weighing 6¼ lb. Here again the clinical picture was unusual.

The patient, aged 44, 3-para, had her last confinement 12 years' previously. She was recommended for admission on account of albuminuria. Her menstrual history was confused but she was quite definite as regards a period of amenorrhœa of eight months' duration. She was so obese and œdematous that it was impossible to make out definite uterine enlargement of fœtal parts. Radiography, however, showed fœtal bones corresponding in size to an eight months' fœtus and the Zondek-Aschheim test was positive. The urine contained albumin (4·12 parts Esbach) and the blood pressure was 150 mm. Hg systolic, 80 mm. diastolic. Despite treatment over 15 days the patient's condition did not improve; in fact, she was growing gradually worse. It was decided to induce labour by means of insertion of a pig's bladder. Under the anæsthetic it was found that the uterus was not enlarged. The passage of a sound confirmed this. No further attempt was made therefore to induce labour.

The patient was operated upon and an advanced intraligamentary ectopic pregnancy was found. The live child was removed and the placenta, which was situated between the layers of the broad ligament, was removed entirely with the sac. There was very little loss of blood. The patient's condition before operation was poor. After operation it became steadily worse and despite blood transfusion and other treatment she died 16 days later. Post-mortem examination confirmed the operative findings and showed peritonitis and chronic nephritis. The child, however, continued to thrive and was discharged a month later.

I wish to thank Dr. R. A. Lennie and Dr. J. Hewitt for permission to publish these cases.

EXCESSIVE SPONTANEOUS INFLATION OF A LUNG CAVITY.

By C. O. S. Blyth Brooke, M.R.C.S. Eng., D.P.H.,
CHIEF TUBERCULOSIS MEDICAL OFFICER, COUNTY ANTRIM.

Ballooning of the lung, a somewhat rare pulmonary condition, was first described by R. Hall[1] as an occasional complication of advanced pulmonary tuberculosis. The condition thus described is one in which the entrance from the bronchus into a lung cavity becomes obstructed in a valve-like manner, presumably with a piece of necrotic tissue, and thus allows the ingress of air during inspiration but prevents the egress during expiration. The cavity being, as it were, pumped up then presses like a balloon on the remaining lung. The symptoms and physical signs produced by this mechanism resemble, in a modified way, those of a spontaneous pneumothorax, to which, in fact, the whole process is very similar. During the inflation of the cavity the walls tend to stretch, and, if they burst, the main and neighbouring cavities break down and enlarge the balloon.

Little interest appears to have been directed to this somewhat rare condition, and I know of no case in which the diagnosis has been confirmed by manometric and radiological examination. The following case, however, suggests that the matter has a practical and therapeutic, as well as an academic, aspect.

A female, aged 21, was admitted to the Massereene Hospital on Feb. 2nd, 1931, as an advanced case of pulmonary tuberculosis. Her history was a typical one, and had lasted for 18 months. During the summer and autumn of the year 1930 she had spent some months in a sanatorium, but had failed to respond adequately to rest. She was further known to have had morbus cordis for some years; mitral stenosis and incompetence, considered to be rheumatic, had been marked for some time, though there had been no obvious evidence of impairment of cardiac efficiency. Tubercle bacilli in large numbers had been found in every recent sputum examination. After admission, she was found to be acutely febrile, with physical signs of infiltration and cavitation in the middle and lower zones on the right side. In view of the extent of toxæmia, it was considered that neither an artificial pneumothorax nor a phrenic evulsion would offer her any material assistance, and no special treatment was undertaken.

On Feb. 18th she developed very severe and distressing pain, fairly consistent in character, on the right side and situated laterally and posteriorly towards the lower costal margin. On examination anteriorly, the percussion note was found to be normal and the breath sounds practically absent on the right side; in spite of the absence of cardiac displacement, first impressions suggested spontaneous pneumothorax. Posterior examination, however, appeared to exclude this, for the percussion note was still definitely dull towards the base, and on auscultation loud cavernous breathing was heard in this region. The pain continued during the next week, until Feb. 25th, and was not fully controlled even by morphia.

On Feb. 25th, finding the physical signs unchanged and suspecting the superinflation of a cavity, I inserted a pneumothorax needle directly through the chest wall posteriorly, in the eighth intercostal space. The manometer indicated a pressure definitely greater than that of the atmosphere, the readings varying with respiration between +4 and +6 cm. of water. The needle, on insertion, was definitely felt to be traversing the several layers of the chest wall, and a further resistance, which would respond to the thickened and necrotic wall of an adherent lung cavity. After the withdrawal of 100 c.cm. of air, the pressure was found to approximate to that of the atmosphere, the manometer readings now varying between +2 and −2. Following the withdrawal of another 100 c.cm., there was found to be no change in the manometer readings, and, concluding that air was entering via the air passages at the same rate that it was being aspirated, the pneumothorax needle was withdrawn. After this procedure there was no marked change in the physical signs, but the pain was found to be somewhat relieved and disappeared within a few hours. The patient continued to go downhill, developed diarrhœa, and finally died on March 30th, without very much comfort and with no recurrence of the pain.

Unfortunately, no radiological examination was possible at the period referred to, though an earlier skiagram, taken elsewhere, in the summer of 1930, which I was courteously allowed to see, showed much infiltration with commencing cavitation in the right lower zone. Unfortunately, again, an autopsy was impossible.

In this case it is clear that there was a ballooning condition of some space in the chest, causing great pain by its pressure on surrounding structures, which was greatly relieved by deflation. It is difficult to exclude the possibility that the needle was really introduced into a localised spontaneous pneumothorax with a thickened visceral pleura, but the following considerations render this unlikely: (*a*) If the pleura had been thickened to such an extent as to cause such impairment of percussion note, adhesions would almost certainly have developed and prevented a pneumothorax of the extent necessary to have accounted for the symptoms. (*b*) The point of the needle definitely felt to be in a large cavity and, further, a large cavity would have been necessary to account for the diminished breath sounds anteriorly; such a large pneumothorax would probably have caused some degree of cardiac displacement. (*c*) The point of the needle, on introduction, definitely felt to be piercing some lung tissue.

In either case it is difficult to account for the loud cavernous breathing heard, but, if dealing with a lung cavity, it might be due either to the continued entrance of air into a nearly contiguous cavity, or to the conduction of sounds directly from the trachea or large bronchi into the stationary air at the end of the

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING IN EASTBOURNE.

PROCEEDINGS OF THE REPRESENTATIVE BODY.

(Concluded from p. 189.)

AN objection to the report of the Council on the problem of the out-patient was raised by Dr. A. H. MACKLIN for Dundee.

Out-patients in Distressed Areas.

He introduced an amendment stating that, under present conditions, there was a considerable class, especially wives and children of insured persons, who were unable to secure adequate medical attention from their own resources, and for whom the only service obtainable was that of the voluntary hospitals, unless they were to be constrained to apply to the public assistance authorities. In his area, Dr. Macklin said, there was much economic depression, and no public medical or contract services were in force. If the Council's report were put rigidly into operation a large number of persons in Dundee who were out of work would be unable to get any treatment at all. That was to say, they would either be forced to go without treatment, or else they would apply for public assistance. As far as the dependants of the insured persons were concerned, it would be difficult to bring them into any insurance scheme later on if they had once acquired the habit of going on the parish. He thought the report should be more elastic in its application to depressed areas. Contract services were not regarded favourably in Dundee, and could not be accepted as a solution.—He was supported by Dr. G. W. MILLER, also of Dundee, who thought it would be advisable to wait until the dependants of insured persons were included in an insurance scheme before adopting this report. As a temporary measure it was preferable that these people should be treated as out-patients than that they should come under the public assistance officer.—Dr. E. R. FOTHERGILL took exception to the wording of the Dundee amendment, which made no reference to economic conditions, and which implied a reflection on the medical practitioners of Dundee.—Dr. E. H. T. NASH described a scheme applying to women and children which was successfully in force in the Thames valley, and which made medical service available to them at a rate approximate to that of National Health Insurance.

Dr. H. B. BRACKENBURY thought that the Dundee amendment destroyed the whole value of the report. The meeting need not suppose if the report were adopted that it would immediately be rigidly enforced. It would simply constitute a basis, similar to the hospital policy, upon which further progress could be founded. Persuasion and education of hospital authorities would naturally be the first steps, and Dundee need not be alarmed for the immediate future.—On this assurance Dr. MACKLIN consented to withdraw his amendment. After some further discussion of minor points the report was approved by the meeting.

Public Medical Services.

Arising out of the report, a resolution was moved by Dr. A. KEITH GIBSON, for Kensington, to the effect that as a practical contribution to the problem of the out-patient the Association should actively assist in the formation of public medical services wherever these were not already in operation. During the preceding discussions, he said, attention had been called to the difficulties of reducing overcrowding in out-patient departments. At first glance it seemed to be merely a question of achieving agreement between the consultant at the hospital and the general practitioner, but actually the boards of management of hospitals would probably feel dissatisfied if much of the hospital out-patient work were to pass into the hands of the private practitioner. If organisations could be built up on the lines of the public medical services which were now active in several parts of the country, they would offer a sound demonstration to boards of management that adequate care could be provided for this large group of persons outside hospitals. Such medical services had the additional advantage of limiting, in some measure, the encroachments of clinics on private practice. Kensington was aware that the feeling of the Association was by no means unfavourable to contract practice of this kind, but it was hoped that the Representative Meeting would be willing to sanction active assistance on the part of the Association in establishing more public medical services throughout the country.

Dr. BRACKENBURY admitted that the Council was certainly favourably disposed to contract services, and said that the Association had even lent sums of money, on occasion, to further their establishment. But there could be no doubt that, whereas some areas were favourable for the foundation of contract medical services, others appeared to be quite unsuitable, and the Council would not feel justified in undertaking a crusade to establish them in every area.—Dr. J. LOCKHART LIVINGSTONE supported the Kensington motion, but Dr. E. WALLACE HENRY said that, in view of Dr. Brackenbury's remarks, it was scarcely possible for the meeting to pass the resolution; at the same time, however, he felt that it was undesirable that the Representative Body should appear to disapprove of the principle by rejecting the motion. He appealed to Dr. Gibson to withdraw the motion. This Dr. GIBSON did not feel in a position to do, and the meeting agreed to pass to the next business.

Consultant Services in Contract Schemes.

Sir RICHARD LUCE moved a recommendation of the Council—

> That any scheme providing consultant or specialist services for patients of the class such as constitute the members of a contributory or other similar scheme, should include the following principles:—
>
> (1) That where it is desired to provide consultant and specialist services for "contributing" patients defined in para. 42 of the Hospital Policy of the Association, a panel of consultants and specialists should be formed.
>
> (2) That all registered medical practitioners who satisfy one or more of the following criteria should have the right to have their names included on the panel: (*a*) That he has held hospital or other appointments affording special opportunities for acquiring special skill and experience of the kind required for the performance of the service rendered, and has had actual recent practice in performing the service rendered or services of a similar character; or (*b*) that he has had special academic or post-graduate study of a subject

obstructed bronchus, the very small proportion of tissue probably forming the obstruction and the stationary air in the cavity.

On the whole, I consider that this case may be definitely accepted as proving by manometric control the occasional existence of a condition of superinflation of a pulmonary cavity, and that associated symptoms may at times be relieved by aspiration of the contained air. Further, there may not necessarily be a recurrence of the mechanism after deflation.

> which comprises the service rendered, and has had actual recent practice as aforesaid; or (*c*) that he is generally recognised by other practitioners in the area as having special proficiency and experience in a subject which comprises the service rendered.
>
> (3) That the decision as to satisfactory compliance with the criteria for admission to the panel should be vested in a purely professional body upon which the different classes of specialist and consultant are adequately represented, and which would be recognised by the profession as securing impartiality.
>
> (4) That there should be an agreed schedule of reduced fees.

The need for such a motion, he said, depended on the action of the Hospital Saving Association, who were trying to arrange special consultation fees for their patients. The hospitals committee felt that it was not in accord with the principles of the B.M.A. that such special rates should be limited to a group of individuals, members of a particular organisation. They had therefore drawn up the above scheme, which was based on four criteria. First, a panel of consultants should be available; secondly, any medical practitioner should be eligible to serve on that panel provided he fulfilled the requirements stipulated; thirdly, a purely professional body should be responsible for deciding whether applicants met these requirements; and fourthly, service should be given at reduced fees.

Dr. A. GREGORY (Manchester) objected to the word "reduced" as applied to the fees asked, since he considered that it would limit unduly the action of those serving on the panel.—Dr. BRACKENBURY considered that the whole point of the service lay in the fact that it was to be given at reduced fees. If there was to be no reduction there might as well be no service.—Dr. N. E. WATERFIELD (Reading) pointed out that what was a reduced fee for some consultants was not necessarily reduced for others; he thought a fixed schedule was essential, but that there was no need to make any reference to reduction.—This view was shared by Dr. W. F. DEARDEN.—It was agreed that "reduced" should be omitted.

Mr. BISHOP HARMAN suggested that para. (3) of the motion should contain some reference to the machinery by which a practitioner might be removed from the panel, and suggested that the paragraph should be referred back to the Council. Although Sir RICHARD LUCE was ready to accept this proposal, Dr. BRACKENBURY thought it was unnecessary, since these were merely the general criteria, and the consideration of further detail might well be postponed until the Association was contracting with another party to provide such a service.

Views were divided. Sir ROBERT BOLAM felt that, as the motion included certain principles it should be possible to find a form of words to replace para. (3) in which it would be set out in general terms that consultants admitted to the panel should abide by the rules laid down for the service. This, however, proved to be much more difficult than he had supposed, and after prolonged discussion the meeting agreed on the following form of words:—

> That there should be vested in a purely professional body or bodies upon which the different classes of specialists and consultants are adequately represented and which would be recognised by the medical profession as securing impartiality, the decision as to satisfactory compliance with the criteria for admission to the panel, and every applicant for inclusion in such panel shall sign an agreement that if admitted to the panel he will abide by the decision of such professional body or bodies as to his continuance on the panel.

Even so, when this appeared as a substantive proposition, certain fallacies were detected in the amendment by some of the more precise logicians present. It proved to be one of those occasions when everyone was agreed on the substance, but universal satisfaction with its expression was not to be won. The meeting finally adopted the complete recommendation of Council as amended by Dr. GREGORY, with the rider that the Council should be asked to consider Sir Robert Bolam's amendment as a possible substitute for para. (3).

Another motion, introduced by Sir RICHARD LUCE, that the Association would be willing to establish or coöperate in the establishment of a panel of consultants in conformity with the principles of the scheme just adopted, arose, he said, out of the action of the Hospital Saving Association previously mentioned. The establishment of a panel in the metropolitan area was contemplated, but before it wa formed an advisory meeting of consultants would be called to consider the details of the scheme.—The meeting supported this motion.

In moving the remainder of the annual report under hospitals, Sir RICHARD said that a positio had been created by the Road Traffic Act, unde which hospitals may claim from an insurance compan an amount for the maintenance and treatment o injured third parties. The Council had issued i January a letter to the secretaries of medical sta of hospitals, recommending the doctor attending t claim a fee from the hospital in these cases. Th British Hospitals Association had been negotiati with insurance companies for a flat-rate payme and had suggested that the Council should not pr for the payment of the medical staff until th negotiations were concluded. The Council, howev had felt that it was not possible to depart from t terms of the January letter, and it was decided th the two Associations should join in inquiry into t future position of medical staffs of voluntary hospit with regard to financial recognition of their servi During the past year, Sir Richard said, the commi had done everything in its power to further acceptance of the revised hospital policy, and th was evidence that the principles of the policy we being steadily adopted.

A motion was introduced by Dr. D. F. TODD, f Sunderland, proposing that the Council should b asked to consider the question of opposing th establishment of closed panels of consultants and specialists, acting at reduced fees, to societies, and bodies, as being contrary to the ethics of the profession; the meeting supported him.

Commission for Introduction of Patients.

Dr. H. C. BRISTOWE (Bristol) brought forward a motion to state that it was undesirable that the Association, or any body under its control, should seek to obtain a commission from a practitioner for the introduction of a patient to any medical practitioner, whether that patient was to be attended in an institution or home, or simply as a private patient. He considered that no lists should be available of practitioners who were willing to pay a premium for patients, and claimed that a list of the kind existed.—Sir ROBERT BOLAM said that the list in question was published by a reputable body, and contained no mention of any practitioner's name. It consisted simply of information about accommodation for residential patients in various homes superintended by medical men, and was a simple trade arrangement for the convenience of any doctor who wished to place a patient in a residential home under medical supervision.—The meeting supported Sir Robert in his view that no question of ethics was here involved.

Mental Illness.

Dr. **Fothergill** proposed that the Council should be instructed to endeavour to secure the acceptance of the principles affecting private practice in regard to mental illness. There was steady encroachment on private practice, he said, from several aspects. It was owing to the increase in the number of whole-time practitioners at antenatal clinics that the national maternity scheme of the Association had been drawn up and approved. Since the passing of the Mental Treatment Act the Board of Control had implied that it was impossible to treat mental illness on the same lines as physical illness. But a sick mind was not necessarily a diseased mind, and the general practitioner should know how to treat those of his patients who were mentally sick—indeed he was legally required to do so with his insured patients. The Board of Control had stated that the medical student had lamentably little opportunity of seeing mental illness, but this was not necessarily the case. Many universities required their students to attend a three months' course in mental disease. The recent appointments to the Board of Control were not such as to establish confidence in the ability of that body to judge this question. Twenty-three applicants for these appointments from the staffs of mental hospitals had been refused. The general practitioner was in a position to know the environment and characteristics of his patient, and to advise him how best to secure the mental rest which he needed. The Board of Control had suggested that all cases of mental illness must be attended at clinics, which would mean that the general practitioner was robbed of his opportunities to acquire experience. The medical profession had been deprived very largely of midwifery and of the care of sick children, and was now in danger of losing the treatment of early mental cases. One of the principles in the treatment of the mentally sick was to keep all thought of an asylum out of the mind of the patient, yet the Board of Control advocated the care of these patients in villas built in the grounds of mental hospitals. He was earnestly opposed to such an idea, and urged the meeting to endeavour to retain the right of attending the mentally sick.

Dr. R. G. **Gordon** (Bath) admitted that many universities gave a three months' course in mental disease, but he asked whether the meeting would consider training in medicine or surgery adequate if it extended over three months without previous instruction in physiology or pathology. The medical student was given little or no instruction in the functioning of the mind. A preliminary training in psychology should be an essential part of a course in mental disease. He held no particular brief for the Board of Control, but it was a body designed to look after the interests of the patient and to see that he was not confined improperly in a mental hospital. The superintendent of a mental hospital, therefore, was not necessarily the best person to sit on such a board. There was no reason why clinics for mental treatment should be staffed by consultants; in his district the clinic was supervised by the superintendent of the mental hospital, attended by a second practitioner for the care of children and young people, and by a third for the care of adults. Not every general practitioner wished to treat mental cases, which were often extremely troublesome. He agreed with Dr. Fothergill that many mentally sick patients were better treated apart from mental hospitals, but he thought it unlikely that the Board of Control would try to herd them into institutions without regard to individual circumstances. It must be remembered, moreover, that there was considerable abuse of treatment of mental illness in small, privately run homes.

Dr. D. **Rice** (East Norfolk) spoke as the superintendent of a public mental hospital. Exception had been taken in some quarters to the recent appointments to the Board of Control, but the difficulty lay in the fact that the Treasury was not offering salaries which would be attractive to men of high standing in mental work. The three months' course in mental diseases which was attended by the medical student usually consisted of a series of lectures and demonstrations which were sufficient to rouse his interest, perhaps, but which barely touched the fringe of mental disease; nor was there an opportunity of repeating the course during training. Under the Mental Treatment Act the patient admitted to a villa in the grounds of a mental hospital would have a better opportunity for recovery than he could hope for while living in a slum. Dr. Fothergill need not fear that the number of those who would be relegated to asylums would be increased; on the contrary, it was hoped that by extending out-patient treatment the actual number of admissions would be reduced. Attending the clinics there would be those patients who had improved sufficiently to leave the hospital, and whom it was hoped to discharge completely, and patients sent up by general practitioners for consultation. Until recently the mentally sick had been unable to obtain treatment unless they were rich enough to pay for care in expensive nursing homes; it was now hoped that early treatment would be available for every case, and that admission to a mental hospital would be avoided in many cases.

Dr. H. M. **Stratford** (Kensington) agreed with Dr. Fothergill that the best person to treat the mentally sick patient was the private practitioner. Common sense and sympathy were the most important components of the treatment, and the shadow of the mental hospital could not fail to do harm.

Dr. E. H. T. **Nash** moved that the whole question should be referred to the Council for investigation and report.—Dr. **Fothergill** acquiesced in the proposal, and added that he was chiefly anxious that the private practitioner and the patient should be kept in touch with each other. At present the patient could attend a mental clinic without the knowledge of his doctor, which was most unsatisfactory. If it were true that the medical student received inadequate training in mental disease then the standard of instruction must be improved. The medical staff of the mental hospital should supply the consultant service for the general practitioner.

Dr. **Brackenbury** said that while it was true that the training of the medical student was bound to be incomplete in many respects, it was not true to say that those general practitioners who undertook the treatment of mental cases were not properly equipped for the task. The general practitioner was not a universal expert, but he knew when it was inadvisable for him to undertake treatment. Although there were instances where the care of mental cases had been shown to be inadequate, it was only in a few isolated cases that a medical man had been found to be responsible for the neglect. With regard to the Board of Control, the Council took no exception to the appointments, but only to the method by which they had been made. The Board had been approached and a suggestion offered that there should be a wider choice in future. It was agreed that the question should be referred to Council.

National Health Insurance.

A motion by Dr. W. D. Williams, for South West Wales, that a patient, referred to a regional medical officer by his doctor, should not be informed of the origin of his reference, was withdrawn upon the explanation by Dr. H. G. Dain that under the present arrangements such information was not given.

Dr. Stratford (Kensington) moved that local divisions should, where necessary, appoint an insurance subcommittee, by way of stimulating interest.—Dr. Dain supported the motion, which was carried.

Dr. Stratford also moved that all questions involving penalties should be removed from the punitive jurisdiction of the Ministry of Health, and should be decided by a medico-legal tribunal constituted for the purpose; failing the constitution of such a tribunal all decisions involving penalties inflicted by the Minister should be subject to an appeal to the High Court. This, he considered, was a vital principle which should have been insisted upon in 1912. At present the insurance practitioner was in the hands of a government department where the Minister of Health had primitive jurisdiction. There was no appeal from his decisions, and no opportunity for protest.

Dr. E. Stungo (Lambeth) pointed out that the insurance committee provided an intermediary between the practitioner and the Minister of Health. In cases of offence by a practitioner the insurance committee was responsible for the formation of an adjudicating body, the medical service subcommittee, which gave the case an impartial hearing before passing on the conclusions reached to the insurance committee, who then made a recommendation to the Minister.

Dr. D. Clow and Dr. D. Roxburgh opposed the motion, and they were supported by Dr. Dain, who said that the disciplinary mechanism had been considerably modified during the last three years and undertook to satisfy the Kensington division that it was just and effective.—Dr. Stratford withdrew the motion.

A further motion was proposed by Dr. Stratford, for Kensington, to the effect that in view of the charges concerning increased certification which have been levelled against insurance practitioners the Council should give expression to practitioners' opinions in this matter, including as the main causes: more sickness, unemployment, earlier recourse to doctor, and growing appreciation of the services and benefits available.

Dr. Dain said that when the National Health Insurance Act was passed estimates were made on the expectation of sickness based on the extremely inadequate statistics of a men's sickness benefit society. During the war there appeared to be little sickness, because the country was engaged in a great united effort. Since the war sickness benefit had steadily increased, and there was a danger of the insurance funds becoming bankrupt. The blame had been thrown on the doctor, with a charge of careless certification, but the Council were satisfied that depressed economic conditions, a false initial estimate, and an improved standard of service were largely responsible for increased claims. Better diagnosis and more elaborate treatment meant better health in the end, but it also meant more sickness claims. The Council was engaged in considering what was almost a charge from the Government, and were preparing a statement in reply which they hoped to issue in October.

With the permission of the meeting Dr. Stratford agreed to refer this motion to the Council, and with it 27 other motions relating to insurance practice which appeared on the agenda paper in the name of Kensington.

Sweepstakes and Charities.

A vigorous discussion was aroused by the motion introduced by Dr. Ernest Ward (Torquay) that complete discretion should be allowed to branches and divisions in regard to the methods they adopted to assist medical charities. Repeated appeals, Dr. Ward said, were made for medical charities, but results were disappointing. It might be desirable that every member of the Association should contribute half a guinea annually, but in actual practice appeals were a failure. At Torquay dances had been arranged and had yielded from £10 to £15, but when a sweepstake was organised the returns reached £650, out of which £400 had been contributed to the Royal Medical Benevolent Fund, £200 to the Epsom College Fund, and £50 to the divisional medical benevolent fund. The Council had expressed disapproval with this method of obtaining money when the sweepstake was half organised, and had, he estimated, lost £35 for charities by their action. Was a sweepstake, he asked, more immoral than a dance?—And added a quotation from Gibbon in which the moral aspect of dancing was very severely dealt with. All that his Division asked was a benevolent neutrality on the part of the Council, allowing independence of thought and action in the divisions and branches.

Dr. J. Livingston (Barrow-in-Furness) said that good results had been obtained in his area by interviewing all the practitioners and securing a banker's order for an annual subscription of a guinea.—Dr. C. E. S. Flemming thought that it was deplorable that the medical profession should have to resort to dances and sweepstakes to secure that provision for dependents which the working man made as a matter of course, either compulsorily or voluntarily. Sweepstakes gave the contributor a false sense of benevolence, and left him with the feeling that a five-shilling ticket could very well take the place of a guinea subscription.—The Rev. S. D. Bhabi (Greenwich and Deptford) considered that sweepstakes were immoral. He suggested that if every member of the Association who was a smoker set one cigarette aside a day, and bought it back again, the proceeds of the sales would amount to a handsome sum for charity in the year.—Dr. C. J. Marsh (West Dorset) said that following the instruction of his division he was bound to vote against a motion which he would prefer to support, but Dr. G. Mackie (Shropshire and Mid-Wales) thought that the profession was in low water if it had to call upon outsiders to support its charities. He thought a round sum might be raised if each member gave up a week's golf annually.

Dr. Brackenbury put forward the attitude of the Council. They agreed that there should be no interference with the individual, but they thought that as long as there was either a majority or a strong minority who held that a certain method of raising funds was indefensible, the Association should not be officially responsible for the employment of that method, and should not be advertised by individual members as being so.

Dr. F. K. Kerr mentioned a new association of medical practitioners which had been formed in Edinburgh, and which had, he said, arranged a system of group insurance; anyone under 25 who entered might have his life insured for £1000 at the rate of £10 a year.

Dr. W. F. Dearden (Manchester) considered that it was impolitic that the name of the Association should be coupled with anything illegal, however universal, and Dr. D. Clow (Gloucestershire) thought that sweepstakes raised in the name of the Association were not consonant with the dignity of the medical profession, or with that of a body intended primarily for the advancement of medical science.—Sir Robert Bolam agreed that it was undesirable that the name of the Association should be used promiscuously, even though it aided medical charities. It was conceivable, he said, that Dr. Ward might find a market for an improved burglar's jemmy, stamped with the name of the Association, which might provide a lucrative source of funds for medical charities, but it would not be a wholly defensible action.—The meeting proceeded to the next business.

The same subject was raised by Dr. J. S. Manson (Warrington) in connexion with the hospital policy of the Association. Sweepstakes, he said, were admitted to be the purest form of gambling. Viewed lightheartedly gambling was a flight—or flutter—from reality, but regarded more seriously it was a subtle and corrupt vice, a perversion of the normal instinct of adventure. He did not consider that it was dignified that the medical and nursing staff of a hospital should be remunerated from the leavings of a sweepstake.—Mr. Bishop Harman pointed out that the promoters of sweepstakes were not afflicted by a sense of dignity, and thought it would not be satisfactory to introduce anything so imponderable into the hospital policy. He foresaw financial loss from the extension of this method of raising money; in Dublin some of the hospitals which had received large sums through the Irish sweepstake experienced the suspension of their regular contribution from the local authority.—On the suggestion of Dr. Dain the meeting passed to the next business.

The Retiring Chairman.

A vote of thanks to the retiring chairman of the presentative Meeting, Dr. C. O. Hawthorne, was posed by Dr. Agnes Bennett and seconded by r. A. B. Murray. Dr. Hawthorne has completed his third year in the chair, which will be taken next year by Dr. E. K. Le Fleming.

Annual General Meeting.

Prof. A. H. Burgess relinquished the chair at the general meeting to Dr. W. G. Willoughby. Dr. W. Harvey Smith, the President, was unfortunately not able to be present. Dr. Willoughby introduced Lord Dawson of Penn as the President-elect for 1931–32. Lord Dawson said that the Association was looking forward to welcoming members in London for the centenary meeting next year.

JOINT SECTIONS OF SURGERY AND MEDICINE.

At a joint meeting of the two sections, presided over successively by Dr. R. A. Young and Mr. C. A. Joll, Sir Thomas Horder opened a discussion on

Treatment of *Septicæmia.*

Sir Thomas Horder defined the subject for discussion as the general infection of the body by the common pyogenic organisms—the "streptococcal or staphylococcal fever" of Ryle—and included the patient with metastases, even though blood culture might be temporarily negative. He excluded the overflow of organisms into the blood stream in pneumonia and typhoid fever. The history of the former expectant treatment was reviewed, the attempts—mostly unsuccessful—to use antiseptics intravenously, the introduction of bactericidal sera, vaccines, sensitised vaccine, and immuno-transfusions with their disappointing results, and, finally, non-specific "shock" treatment, which is still on trial. Wise expectant measures, said Sir Thomas, are still our main standby. Treatment to be effective should be institutional, and comprises rest, fresh air, food, abundant water, sun (natural or artificial), eliminative measures for bowels and skin, alkalis and glucose to combat acidosis, hæmatinic drugs to control anæmia, nucleic acid and other leucocytic stimulants, hydrotherapy to control pyrexia, proper sleep, relief of pain by local and general means, and, above all, good nursing and a confident helpfulness from the doctor. Bactericidal serums, vaccines and immunogens had all been disappointing. Sensitised vaccines had been used, and also immuno-transfusion, but ten years of trial left them without much credit. Bacteriophages had been commercialised and were under consideration. The immunological factors between host and infecting organism were still generally undetermined. Antitoxic serum offered some hope. *Chemotherapy* had provided many failures and some disasters. Mercurochrome, despite its dangers, had some supporters. Some of the good results claimed from immunotransfusion might be due to the relief of the anæmia, to benefit derived from the donor's blood, or to a form of non-specific protein shock. Any form of non-specific treatment should probably be reserved for the later stages of the disease, and even then adopted with caution. Chemical shock with S.U.P. and other agents had been employed. There were so many things to do which involved no speculation, that this measure was best left to those who understood the teaching upon which the practice was based. The primary focus and later metastases should be searched for daily, and treated by aspiration for preference, or, if this were unsuccessful, by incision and drainage.

Sir Thomas Horder concluded with general advice. Study the individual case; mobilise expectant measures at the earliest possible moment; work in concert with the bacteriologist, but do not take his cue in regard to the programme of treatment; never put all the therapeutic eggs into one basket; steadily persist with the plan of campaign decided upon; avoid panic; do not flog the patient by too many treatments.

PROPHYLAXIS ASPECTS.

Sir William Wheeler referred to the prevention of septicæmia by general surgical technique—e.g., excision and irrigation of severe war wounds. There were weak links in the chain, such as the nursing of septic and clean patients by the same nurse, and the possibility of hæmolytic infections from the throats of unmasked spectators. Serum, collosol, iodone, and salvarsan had been given intravenously but were not highly effective. He had no belief in mercurochrome or gentian violet. Injudicious early interference before a protective cellular barrier had formed round the infection might be highly dangerous. He had seen four patients die of septicæmia after unwise early incision into a septic lip, and death from a pimple on the face infected during shaving. In severe cases the continuous giving of glucose, up to 3 litres a day, given drop by drop into the tissue of the breast or into the saphenous vein, was of great value, as was also open-air treatment.

Prof. D. P. D. Wilkie deprecated premature interference with punctured wounds; if the hand was acutely septic with red lines in the arm, antistreptococcal serum should be given at once and Bier's bandage applied constantly with the pressure adjusted until it relieved pain. This treatment was of value before much cellular change had occurred. He was absolutely sceptical of the value of vaccine, but thought sensitised vaccine might be of use. Glucose, given if necessary, subcutaneously or rectally, was valuable. A localised or "fixation" abscess was of good import. When improvement followed collosols there were always other factors to which one could attribute the success. Before operations on the lower bowel, immunisation with *coli* and staphylococcus vaccine three and ten days in advance, and nucleic acid the night before the operation, were of value.

STREPTOCOCCAL AND STAPHYLOCOCCAL ANTI-SERA.

Dr. **R. A. O'BRIEN** spoke on the utility and limitations of anti-sera, and offered an explanation why the reports of the use of antitoxic sera ranged from "enthusiastically favourable" to "no effect." Okell and Parish, from work with several thousand rabbits, had shown that while the toxin of the hæmolytic streptococcus, given intravenously, would kill rabbits, those given antitoxin withstood the toxin and remained in good health. With culture the story was different; living culture given intravenously also killed, and rabbits protected with 0·25 c.cm. of serum could stand the injection of culture without immediate harm, but if one kept them a fortnight metastases occurred and eventually most of them would die. Clearly then, said Dr. O'Brien, antitoxin protected against the toxin of all hæmolytic streptococci whether derived from scarlet fever, tonsillitis, puerperal fever, or erysipelas, but neither antitoxin nor "antibacterial" serum was effective against metastases. Therefore, antitoxin should be given at the earliest moment, intravenously, and in large doses to combat the early toxæmia of patients which often killed. Antitoxic serum against the staphylococcus had just become available. Its action apparently resembled that of streptococcal antitoxin, for it protected rabbits against a certainly lethal dose of toxin given intravenously; highly promising clinical results had been reported and further experience was desirable.

GENERAL DISCUSSION.

Mr. **N. E. WATERFIELD** had himself suffered from a septic infection of the finger. The same evening he was very ill and the finger was incised during the night and again next morning; the many incisions greatly relieved the pain. With antistreptococcal serum, abundant fluid and nursing out of doors, he made a good recovery.

Dr. **R. KELSON FORD** spoke of unrevealed bacteriæmia, a condition of equilibrium between host and microbe, the disturbance of which resulted in local infection—e.g., tuberculous joints. A woman patient in advanced pregnancy had knocked her knee against a bed; though the skin was unbroken, an inflamed lesion occurred below, and by aspiration a culture of hæmolytic streptococcus was obtained. This, he considered, was an instance of potential "idiopathic" puerperal sepsis. He gave vitamin A freely to pregnant patients; colloidal silver intravenously and milk intramuscularly had proved useful.

Dr. **D. S. SUTHERLAND** used streptococcal antitoxic serum in early puerperal sepsis, for he had had good results in toxic scarlet fever. He had an experience of several hundred cases of puerperal sepsis admitted late to hospital; for these cases he favoured L. Colebrook's mild arsenical treatment, the drug being given intramuscularly to provide slow absorption.

Colonel **R. S. TOWNSEND** had had complete failures with mercurochrome and acriflavine in India, where he had treated at least 50 cases. He favoured antistreptococcal serum and, in early punctured wounds of the finger, Bier's treatment.

Dr. **FLORENCE STONEY** advocated zinc ionisation and diathermy.

Mr. **G. H. STEELE** protested against the curt dismissal of transfusion. He had seen dramatic improvement follow transfusion in a patient gravely ill with so many staphylococci in the blood that they were visible in smear and grew profusely in culture. In another patient with streptococcal blood infection from a septic bone in the leg secondary hæmorrhage had occurred. Improvement after transfusion was immediate.

Mr. **R. V. HUDSON** found abundant fluid, fruit juice, and vitamin A of value. During septicæmia, when effusion occurred into joints or pleura it was unwise to do more than aspirate at first. The fluid teemed with cocci and, therefore, he thought it wise to treat this collection as a "fixation abscess" and aspirate only. Bier's treatment was not always successful. At autopsy, following a witlow, he had found streptococci in the serous fluid of the che and in the thrombosed vein of the arm which had been incised to the elbow.

Mr. **C. A. JOLL** pointed out the importance of keeping a clear judgment. The importunity of friends and the surgeon's own anxiety led him to use many treatments; the last one used got the credit if the patient recovered. He endorsed the value of Bier's treatment, and if he pricked his own fing applied a bandage at once. He had saved a pati desperately ill with osteomyelitis by amputati Transfusion he found of great value, sometim alternated daily with blood-letting. Glucose 10 per cent. solution, and insulin if necessary, w of value.

Dr. **R. A. YOUNG** reviewed the discussion. considered that the laboratory worker had th future of this condition in his hands; he must to find why some cases of septicæmia died in a hours, others lasting weeks or months; these va tions might be related to the peculiar *strains* organism present or to the different response of di ferent patients. He feared too early opening of infected fingers, and had seen death follow injudicious extraction of teeth, particularly from elderly people. In 1918, during the influenza outbreak, he had always begun to hope, even in a desperate pneumonia, when he saw an empyema develop; so in septicæmia he felt more hopeful when a fixation abscess occurred. He would aspirate rather than drain. He had a horror of even small pustules on the upper lip, and had seen disaster follow such infections.

REPLY.

Sir **THOMAS HORDER** agreed with the very early use of serum in liberal dosage. He had seen Bier's treatment relieve the pain in punctured wounds. Morphia also helped in the early stages. Many years ago, during an autopsy on a patient dead from infection with hæmolytic streptococcus, he himself thought he had pricked his finger but could find no hole in the glove, even after filling it with water. Next morning the finger throbbed and he was feverish. By the evening the pain was intense and lymphangeitis was present in the arm. He was relieved when his senior surgical colleague incised the lesion. After many painful surgical procedures he recovered, but the finger was still somewhat crippled. He noted that the serum of which Dr. O'Brien had spoken was antitoxic and could be proved in the laboratory to have a protective action which was lacking in the older antibacterial serum. Transfusion certainly helped to combat anæmia. The good effects which had been recorded might be due to some unknown form of "protein shock." The final conclusion was that one must be wise in general judgment, neglect no useful measure, and be alert to find foci.

SECTION OF PATHOLOGY.

AT the meeting of this section held on July 22nd the chair was taken by the President, Prof. E. P. CATHCART, and Dr. E. F. HOARE opened a discussion on

General Practitioners and Coroners' Post-mortems.

He submitted that the work of coroners' post-mortems was peculiarly work for a skilled and trained pathologist, and that many practitioners did not like having to do it. Even those who were eager for the work had very few chances to gain experience. He declared that the legal fiction of the equality of all practitioners applied only to their legal status and their potential abilities. Their particular superiority in any branch depended on opportunity and experience. The legal aspect and intricacies of the Workmen's Compensation Act and general insurance required constant practice if they were to be fully grasped. In the High Court pathologists were more likely to be regarded as experts and their opinions accepted as "evidence." The whole subject, he said, involved a number of complexes, lay and medical. The public held very varying attitudes towards the post-mortem examination, but the medical complexes surpassed all others in complexity. They were composed of self-interest, high ethical considerations, etiquette, illogicalness, stupidity even, combined with intelligence, decent feeling, and practical common sense; the whole producing in their legal brethren's minds the kaleidoscopic effect of being hit on the back of the head by a charabanc. The coroners' complex had, Dr. Hoare thought, been exaggerated. Doctors were often touchy about trifles, and did not realise that coroners were more often than not their best friends. More doctors ought to qualify for coronerships; the coroner's office was tending more and more to be a medical affair. The extended powers under the Coroners Act, 1926, threw a great responsibility on the coroner. He relied entirely upon the post-mortem report, which was not evidence on oath, and which must therefore be absolutely accurate, informing, and reliable in every detail. A coroner's post-mortem examination was not only held to ascertain the cause of death; the coroner was much more interested in how the deceased came by his death. The cause and the "manner how" were co-related, but were not one and the same thing. Many minor points might indicate the "manner how," as well as affording evidence of identification and of crime. The handling and correct interpretation of morbid changes, and the actual performance of the post mortem in a way satisfactory to the demands of the community, could only be acquired by special training and retained by constant practice. There were not enough cases for everybody to have this practice, and the efficiency of the work would be increased, and the public would be better served, by transferring this branch of medicine to pathologists.

A communication was read from Dr. G. ROCHE LYNCH. He agreed that the conduct of the autopsy and the proper interpretation of results could only be satisfactorily achieved by those who had made pathology their special study, and that accurate and reliable evidence was essential if justice were to be administered. The general practitioner would suffer no deprivation, because the demonstration of a case by a competent pathologist was of much greater value to him than actually performing the post-mortem. The employment of specialists had come to stay.

CASES OF POISONING.

In cases where death was due to some poisonous or noxious substance the material would usually be sent to a public analyst or specialist. The employment of a non-medical analyst seriously embarrassed the work of highly skilled men. The average practitioner might see one case of criminal poisoning or drug abortion in a lifetime. The post-mortem might fail to reveal the cause of death on account of faulty observation or on account of the need for bacteriological, microscopic, or chemical examination. This class of case must be dealt with by the expert pathologist. During the autopsy evidence of poisoning might be found, and here often the medical man was in a difficulty. Only persons of experience could properly reserve material for examination; the inexperienced sometimes made ludicrous mistakes which could have serious consequences. Cases of industrial poisoning might present even greater difficulties; important questions depended on the opinion of the pathologist. For the advancement of toxicology it was essential to have plenty of material for investigation and accurate observation and inference.

Dr. H. W. WEBBER opposed the proposal to centralise post-mortem work. He thought that indolence played a large part in the attitude of the practitioner towards this problem. A general practitioner worthy of the name would undertake all branches of practice, calling on the specialist only for difficult cases. If he had not sufficient knowledge for the work he should set to and acquire it. Post-mortem examinations were the foundation of sound diagnosis. He suggested that a mortuary be established in every city and large area, so that relatives might be spared the unpleasantness of having an autopsy in a private house.

Dr. A. J. HAWES said that, although a general practitioner, he held the view that most general practitioners should not do post-mortems. He declared that they could not do them properly, and could not be expected to do them properly. He regarded the outcry of "more work taken away from the general practitioner" as foolish. If the proper person to do a certain task was a specialist, then the general practitioner ought to cease doing it. The only justification for the general practitioner's existence was that he could do many things as well as other people; an autopsy was not one of those things. The speaker had no sympathy, he said, for the "poor old general practitioner" school of thought. It was true that specialism had captured some of the general practitioner's work, but every advance in knowledge had opened up rich new pastures for him. The general practitioner was shifting ground, not losing it. He had not the special education or the necessary opportunity to become sufficiently experienced in pathology to do this work really well. In every other branch of medicine constant practice was considered indispensable, but the average practitioner only did two or three post-mortems a year. A man who opened a cadaver was in much the same position as the surgeon who opened an abdomen; he ought to be able to deal competently with anything he found inside—easy or difficult. The suggestion that the practitioner should do the work and call in the pathologist when he got into difficulties was not likely to be very welcome to the pathologist. While most general practitioners should not do autopsies, some of them should—preferably younger men who liked the work, in small towns and rural areas where there were no pathologists. Another long-overdue reform was that there should always be an assistant doctor at post mortems, just as there was an assistant surgeon at operations. In country districts it was no light task to find the necessary help. The junior could thus learn the work, as well as being of great assistance to the senior.

Colonel H. A. **Smith** considered that the medical curriculum only fitted a man for the merest preliminaries. It was more important that the general practitioner should be certain of ante-mortem conditions than that he should be able to perform autopsies. The district medical officer in India had to do many post-mortems, and often to face strict cross-examination. A medical witness who gave a straight, honest answer and knew his job would not, however, encounter much trouble with a lawyer.

THE NEED FOR A SPECIALIST.

Prof. A. **Murray Drennan** agreed with Dr. Hoare's conclusions, and said that in his experience practitioners did not want post-mortem work. An autopsy might be a very difficult investigation involving pathological, chemical or histological work, and the life or liberty of an individual might depend on the result. Very important details could easily be overlooked by a doctor who was out of touch with such special points. Even the pathologist needed special experience of medico-legal work. Any medical practitioner could do a post-mortem, but he could only be an expert after special study and long experience.

Dr. P. G. **Stephenson Davis** pleaded that, as a general practitioner was often unable to leave his work to attend a post-mortem, he should as of right be given a fairly full report on the examination of any patient of his who came to autopsy. The coroner in his district—a large London division—had agreed, as an experiment, to answer questions on the cause of death. This, however, was not sufficient.

Dr. W. G. **Barnard** maintained that personal attendance was the best solution, and that a report was not a good substitute. No London coroner or pathologist would have the slightest objection to the presence of the general practitioner at the post mortem. The last speaker did not realise how much the pathologist had to do for his two guineas.

Dr. **Davis** suggested that the practitioner might have a carbon copy of the pathologist's report.

Dr. **Barnard**, continuing, agreed that something of the kind might be done. He considered it dangerous for the general practitioner to carry out a post mortem; often the most important part of the operation was the taking out of the organs, the appearances when they were taken out, and the condition of affairs in situ. An unpractised man might destroy all the evidence and be unable to say, for example, whether the clot was ante-mortem or post-mortem. A medico-legal institute was badly needed in this country.

Dr. A. G. **Shera** stressed the importance of an accurate history and of the presence of a clinicia if possible. The general practitioner ought to receive a fee for supplying an accurate clinical history or for attendance—which might usefully be made compulsory—at the post-mortem.

Dr. H. W. C. **Vines** testified as an examiner that few qualified practitioners could write a post-mortem report. He taught students to open and close the body as well as to examine; the reason why many general practitioners did not like post-mortems was their inability to deal tidily with the body. It was very difficult for a student to do more than two post-mortems during his clerkship.

Dr. A. H. **Hunt** mentioned the trials of medical officers in India who were always expected to state the cause of death. Statistics showing the average proportion of cases in which the cause of death was not apparent would enable them to avoid undeserv blame.

Dr. C. W. **Cunnington** pleaded for coöperati between the general practitioner and the pathologis

Dr. **Hoare** replied.

REVIEWS AND NOTICES OF BOOKS

Gastric Acidity.

A Historical and Experimental Study. By J. D. Robertson, M.D., Assistant Chemical Pathologist to the Middlesex Hospital. London: Published for the Middlesex Hospital Press by John Murray. 1931. Pp. 76. 5*s.*

This monograph contains a scholarly review of the history of gastric analysis and observations on gastric secretion, from the work of van Helmont in the sixteenth century down to the present day. If it be remarked that some very notable observations, such as those of Carlson, have been omitted, it must be noted, on the other side, that a large amount of important experimental work which is usually overlooked, such as that of Spallanzani and Réaumur, is here brought out in its true perspective. Perhaps the chief object of Dr. Robertson's monograph is to demonstrate the significance of the occurrence of lactic acid in the gastric contents, and particularly the diagnostic value of the presence of this substance in cases of suspected carcinoma of the stomach. Much has been written on this subject, and many observations have been based on insufficient evidence, and without the necessary foundation of knowledge of previous experiment, so that Dr. Robertson's critical book should be of value alike to pathologists and clinicians who are interested in gastric analysis.

Dr. Robertson is definitely opposed to the view that lactic acid is produced specifically in carcinoma of the stomach. In a series of experiments, so thorough as to leave little doubt as to their conclusiveness, he finds that whereas lactic acid is usually present in carcinoma of the stomach, it is not an early sign; when this acid makes its appearance, the growth is usually too advanced to be amenable to therapeutic measures. He is convinced that lactic acid is valueless for the purpose of making an exact or quantitative interpretation. The production of this valuable monograph at the low price of 5*s.* does credit to the Middlesex Hospital Press.

The Chemical Activities of Micro-organisms.

By A. J. Kluyver, Professor of Microbiology, Technische Hoogeschool, Delft. University of London Press, Ltd. 1931. Pp. 109. 4*s.* 6*d.*

We welcome the appearance in book form of the lectures given by Dr. Kluyver in London in May, 1930. These lectures, which were greatly appreciated by all who were privileged to hear them, have now been collected into a small volume together with many tables and diagrams, and an excellent list of references. The first lecture deals with alcoholic fermentation, and Dr. Kluyver shows how this apparently amazing process can be reduced to a chain of primary reactions. In his second lecture he goes on to consider other physiologically equivalent fermentation processes, and in the third lecture gives a clear and interesting account of oxido-reduction processes. This is a valuable book.

The Principles and Practice of Perimetry.

Third edition. By LUTHER C. PETER, M.D., &c., Professor of Ophthalmology in the Graduate School of the University of Pennsylvania, &c. Philadelphia: Lea and Febiger. 1931. Pp. 315. With 104 engravings and five coloured plates. $4.50.

THE importance of perimetry, both in ophthalmology ind in neurology, has been increased of late years. Dr. Peter points out that visual acuity in different reas of the field varies not only qualitatively (different reas for different colours), but quantitatively, ecording to the strength of the stimulus. Ferree nd Rand, whose perimeter is specially adapted for cientific work of this kind, have shown that if the ntensity of the red and blue stimuli is properly ncreased, these colours may be recognised as far in he periphery as a white stimulus, whereas green alls far short of the red and blue limits, even if the ighest intensity is used. For the peripheral fields he perimeter—consisting of the arc of a circle, so rranged as to secure ease in central fixation, adequate lumination, and contrast of the test object with the urrounding field—is well adapted, but McHardy's odel, which used to be the most popular, is adversely iticised by the author. He prefers his own or the ter model, but maintains that for accurate work re is nothing to compare with that of Ferree and nd. The central parts of the field—central and aracentral scotomata—can be tested more atisfactorily by Bjerrum's screen, or some similar angent screen, at one or two metres, since the scale n which the observations are taken is larger. Even a small-distance scotometer such as Bishop Harman's, in which the test object is only 33 cm. from the eye, gives better results for central scotomata or enlargement of the blind spot than McHardy's perimeter, since the mechanical registration in the latter necessarily reduces the scale of the chart. Mechanical registration nowadays is not looked upon with favour, for this and other reasons, but though it involves more trouble for the surgeon who is taking the test it also has the advantage that it cheapens considerably the cost of the instrument. In these instruments there is no mechanism for moving the test object, which is moved by the surgeon's hand in whatever direction he likes. In the realm of pure ophthalmology, perimetry is chiefly employed in such diseases as glaucoma, retinitis pigmentosa, arterial obstruction, retrobulbar neuritis, toxic amblyopia, and optic atrophy. For the neurologist the limitation of the visual field is an essential part of the diagnosis in the localisation of cerebral affections which involve the visual path. In these various connexions this book will be of great service. Quite half of it is concerned with the special pathology of fields resulting from affections of the nerve head, the optic nerve proper, the chiasm, and the posterior part of the visual pathway, including the optic radiations and the visual centres in the occipital lobes.

Modern Treatment of Nasal Catarrh.

By A. LOWNDES YATES, M.D. Lond., F.R.C.S. Edin., Assistant Surgeon, Ear and Throat Department, Prince of Wales's Hospital; Assistant Surgeon, Central London Throat, Nose and Ear Hospital. Modern Treatment Series. General editor: F. G. CROOKSHANK, M.D., F.R.C.P. London: Jonathan Cape, Ltd. 1931. Pp. 160. *5s.*

IN this little book Mr. Lowndes Yates describes the course of inflammatory processes within the nose and nasal accessory sinuses, and the reactions of the tissues of these regions to infection. He takes rather novel and unorthodox views of some of these processes, and expresses them dogmatically. Thus he states emphatically that ciliary action is the only method by which the sinuses can empty themselves of secretion, and allows nothing to drainage by gravity or to the currents of air across the ostia produced by blowing the nose. Ciliary action is doubtless of great importance when the mucosa is coated by secretion, but, in a cavity of the shape and size of the maxillary antrum, full or half-full of fluid, it is hardly conceivable that the action of the cilia is sufficiently powerful to lift this bulk of fluid to the ostium. Mr. Lowndes Yates considers it wrong to make a wide permanent opening in the inferior meatus to drain a chronically suppurating antrum, a conclusion which is at variance with the general experience, but relies on frequent syringing by repeated tapping or through a small opening made for the introduction of a cannula. This small opening was in vogue in the early days of rhinology, and was abandoned as unsatisfactory in chronic cases, for it was found that suppuration often recurred after the opening had closed. Mr. Lowndes Yates adopts a rather hopeless attitude towards cases of toxin absorption from a focus of infection in the nose; in his opinion operation should be ruled out in these cases, since they become worse instead of better when extra trauma is added to the existing state of inflammation. There is much value in his insistence on the importance of the function of the cilia, and on the necessity of conserving this as far as possible in all operations on the nose. The book is one of a series intended especially for the general practitioner, but it will be of more interest to rhinologists, to whose thoughts on old problems it may give new direction. It is more concerned with ætiology and diagnosis than with treatment. There is a bibliography at the end of each chapter, the usefulness of which would have been enhanced by references in the text.

Clinical Electrocardiography.

Fifth edition. By Sir THOMAS LEWIS, M.D., F.R.S., D.Sc., F.R.C.P., C.B.E., Physician on the Staff of the Medical Research Council; Physician in charge of Department of Clinical Research, University College Hospital. London: Shaw and Sons, Ltd. 1931. Pp. 128.

THAT there is a continued demand for Sir Thomas Lewis's small book on electrocardiography is shown by the appearance of a fifth edition only three years after its predecessor. The demand is not surprising, for electrocardiography has now an established place in the diagnosis of heart disease and all are expected to be familiar with the ground-work of the subject. This book supplies the information required in an extremely attractive form. A new diagram has been

THE TREATMENT OF SEPTICÆMIA.

THOSE responsible for the choice of a programme at the Eastbourne Meeting of the British Medical Association did well to decide upon a joint discussion on the treatment of septicæmia. Contributors to the discussion were wise enough to limit their remarks to those general infections of the body caused by the streptococcus and the staphylococcus. Sir THOMAS HORDER reviewed the unsuccessful attempts to use antiseptics intravenously, also treatment by sera, vaccines, immuno-transfusion, and finally non-specific "shock" treatment. He pointed out that treatment to be effective should be institutional, and comprises rest, fresh air, food, abundant water and glucose, sun, hydrotherapy, proper sleep, relief from pain, and above all, good nursing. The primary focus and later metastases should be searched for daily, and treated by aspiration or drainage. Many speakers brought out useful points concerning the preventive aspects of septicæmia. Sir WILLIAM WHEELER referred to excision and irrigation of severe war wounds and to weak links in the chain of aseptic technique. He stated his conviction that injudicious early interference, especially with a punctured wound before a protective cellular barrier had formed around it, may be highly dangerous. He had seen four patients die of septicæmia after unwise early incisions of boils round the lips.

Dr. R. A. YOUNG, who presided, feared too early opening of infected fingers, and had seen death follow injudicious extraction of teeth, particularly in elderly people. His horror of even small pustules on the upper lip was well founded, for he had seen disaster follow such infections. Prof. D. P. D. WILKIE has used vaccine treatment as a preventive of septicæmia before operation for excision of the rectum. He attempts immunisation with *coli* and staphylococcus vaccine three and ten days in advance, and gives nucleic acid the night before the operation to stimulate leucocytosis. He uttered a warning against the deep-seated metastatic abscess which often occurs with little or no pain. He deprecated premature interference with punctured wounds and stated his view that if a hand was acutely septic and showed lymphangitis antistreptococcal serum should be given at once and Bier's bandage applied constantly with the pressure adjusted until pain was relieved. Mr. C. A. JOLL and Colonel R. S. TOWNSEND endorsed the value of Bier's treatment, but in Mr. R. V. HUDSON's experience it is by no means always successful. Many speakers spoke highly of the results of blood transfusion, but no particular advantage was claimed for immuno-transfusion. Many experiences of complete failure with mercurochrome and acriflavine were recorded. It was rarely made clear by speakers whether the sera which were claimed to have good effect if used early and in large doses were antibacterial or antitoxic sera. It is doubful whether the audience was clear about the difference between an antibacterial serum produced by the inoculation of an animal with the streptococcus itself and an antitoxic serum produced by the inoculation of the animal with the toxin filtered off from a culture of streptococci. Sir THOMAS HORDER did state definitely that both antibacterial and antitoxic sera had been advocated in the treatment of septicæmia and that the latter offered some hope. Dr. YOUNG, reviewing the discussion, wisely left the future of the treatment of septicæmia in the hands of the laboratory worker whose task it is to explore the reasons for the remarkable variations in reaction to infections.

Dr. R. A. O'BRIEN made an illuminating contribution to the laboratory aspect of the subject. H emphasised the desirability of the early use of concentrated scarlet fever antitoxin, since i protects against the toxin of all hæmolyti streptococci, whether derived from scarlet feve tonsillitis, puerperal fever, or erysipelas. In hi view patients might be saved from the earl toxæmia of septicæmia by giving this antitoxi intravenously in large doses at the earliest possibl moment. He struck a further hopeful note in h statement that antitoxic serum against the staphy lococcus had just become available. C. C. OKEL and H. J. PARISH had shown, he said, from t use of several thousand rabbits, that while the tox of the hæmolytic streptococcus, given intravenousl would kill these animals, those given antitox withstood the toxin and remained in good healt Living culture given intravenously also kill rabbits, but animals protected with 0·25 c.c of serum could stand the injection of culture wit out *immediate harm, though if they* were kep fortnight metastases occurred, and eventually m of them would die. His statement that nei antitoxin nor antibacterial serum was effec against metastases is the probable explanat why reports on the effects of sera range from t *most enthusiastic to the most pessimistic.*

The stories of personal experiences were ente taining. Two speakers praised the early use o serum, and agreed that surgical incision w welcome from the great relief of pain which i brought. It was also interesting to hear ho PFANNENSTIEL, operating upon a pyosalpinx punctured his finger, developed lymphangitis rigors, and delirium, and died in spite of the ministrations of BIER. The fact that PAGET gave morphia a high place in the treatment of his own septicæmia was also illuminating; but must we subsist on impressions and reminiscences? Where are the facts and the figures? Surely our great hospitals can arrange investigations by which the effects of blood transfusion in septicæmia can be appraised statistically. Cannot Bier's hyperæmia for punctured wounds of the finger be put to the test in a given series of cases with controls? Is nobody yet prepared to give figures as to the effect of vitamin A in a long series of cases of septicæmia? Why is it not possible for controlled investigations to be carried out on the relative values of antitoxic and antibacterial sera? Concentrated scarlet fever antitoxin has now been available for many years, and the work of OKELL and PARISH was published as long ago as 1927. We are proud of our medical schools and the methods by which they turn out experienced clinicians, but the next step to progress is surely the endowment of definite lines of research in our great hospitals. We look forward to getting results from such centres as the newly endowed wards and laboratories of Queen Charlotte's Hospital, which should replace haphazard impressions with definite facts.

MATTER.

WE are all now thoroughly accustomed to the revolutionary ideas about the live world of animals and plants which matured during the first half of the nineteenth century, and found popular and convincing expression in the "Origin of Species." Man's place in nature is now recognised everywhere as something quite different from the conception of 100 years ago. LYELL'S argument that the surface of the dead world on which he moves has been moulded to its visible form by slow evolutionary processes has also met with such general acceptance as to be a commonplace. It is difficult indeed for us to look at the world about us with other than evolutionary eyes. But of matter itself no one until recently had any doubts; the substance of the universe might change, might go through many combinations and associations, might present entirely different appearances at one time and another, but everyone believed that it was essentially permanent, incapable either of annihilation or creation. It seems now that this too is in doubt, as Sir JAMES JEANS sets out with his accustomed clarity in a supplement to *Nature* of July 18th.

According to modern conceptions an atom of a chemical element consists of one or more electrons revolving rapidly round a nucleus consisting of one or more protons. The fall of an electron towards the nucleus results in the emission of radiation, and such a degradation of electronic orbits with the resultant annihilation of the atoms involved might be a tremendous source of energy. There have been many speculations as to the precise source of the energy represented by the light and heat coming from the sun and stars. Sir JAMES argues that nothing but the annihilation of matter can account for so much energy coming for such a long time from such relatively small bodies. The difficulty is to account not so much for the intensity of the radiation as for its duration, and astronomical considerations almost all converge to the conclusion that the stars in general have already lived through millions and millions of years. Great interest has been aroused of late by the discovery of the highly penetrating cosmic radiations which reach the earth from space and apparently have no immediate connexion with the stars as they exist. These radiations have just the characters which would result from the annihilation of matter. Produced at extremely high temperatures in the interior of stars this radiation would be continually softened in its passage outwards to free space and would finally emerge in the familiar form of starlight. Produced in the surface layers of stars at lower temperatures or in unattached atoms and molecules in free space, it would reach us largely in its original form as cosmic radiation. These radiations, too, are absorbed with such difficulty that they are relatively indestructible; calculations which we can admire without understanding them show that they would still exist in abundance if they had been produced only in the early years of the existence of the universe. Space, in other words, is permeated by nearly all the cosmic radiation which has been generated since the world began; the rays come to us from the remotest eras of time as well as from the farthest depths of space. There is indeed no knowing whether matter is being annihilated now or not. We cannot produce cosmic rays on earth, and hence it may be presumed that the physics which prevail out in the far depths of space and time are different from our terrestrial physics. The destruction of matter cannot at any rate be going on in our own earth to any great extent, for if it were the world would be much too hot for live things to exist.

So much for the destruction of matter, with which Sir JAMES JEANS is mainly concerned. There is, however, something to be said for its creation by the synthesis of electrons and protons, somewhere in space and under conditions of temperature which may be assumed to be the reverse of those favourable for its destruction. Prof. R. A. MILLIKAN in particular has argued that the cosmic rays arise, at any rate in part, from such syntheses as would be involved in the formation of helium from hydrogen. Some such conception would harmonise with the idea of a universe which has had no beginning and will have no end, and might be taken to represent in the dead world what life, death, and evolution are in the live world. Who can tell?

CONTROL OF ASBESTOS DUST IN INDUSTRY.

DISCLOSURE of the ill-effects exerted on the lungs of workers by asbestos dust[1] raised new problems in improved ventilation for dust suppression in asbestos textile factories. These problems have been surveyed by Home Office inspectors and employers concerned; and a report[2] embodying agreement on the danger points and methods of dust control has just been issued. The document is well illustrated, and sets out clearly the technique required for dealing with the unusual difficulties with which the asbestos trade is faced. At the same time it shows how far methods have improved in recent years for capturing dust at its point of origin and preventing it from escaping into the atmosphere of workplaces. It is unfortunate that explanation of the excellent plates can only be found by hunting through the text of the report. While a practical solution of the asbestos dust problem is here presented, it is noted that considerable time will be needed before the recommendations made can be carried out. Meanwhile, asbestosis must occasionally occur as a cause of occupational fatalities.

ANNOTATIONS

THE BRITISH ASSOCIATION CENTENARY MEETING.

In the early part of 1831 Dr. David Brewster, F.R.S., proposed to John Phillips, a geologist, who was then secretary of the Yorkshire Philosophical Society, the establishment of a "British Association of men of science." Phillips enlisted the support of his society, and interested some influential citizens of the town, and on Sept. 26th, 1931, the first meeting of the Association took place in York, 325 members being enrolled. The avowed objects of the Association then laid down have remained unchanged: "To give a stronger impulse and a more systematic direction to scientific inquiry; to promote the intercourse of those who cultivate science in different parts of the British Empire with one another and with foreign philosophers; to obtain more general attention for the objects of science and the removal of any disadvantages of a public kind which impede its progress." The Association holds annual meetings in towns in the United Kingdom or in the dominions. The centenary meeting this year (Sept. 23rd to 30th) will be the first to be held in London. The president will be Lieut.-General J. C. Smuts, F.R.S., supported by the following presidents of sections: Sir J. J. Thomson, F.R.S. (Mathematical and Physical Sciences), Sir H. B. Hartley, F.R.S. (Chemistry), Prof. J. W. Gregory, F.R.S. (Geology), Prof. E. B. Poulton, F.R.S. (Zoology), Sir Halford Mackinder (Geography), Prof. E. Cannan (Economics), Sir J. A. Ewing, F.R.S. (Engineering), Prof. A. R. Radcliffe-Brown (Anthropology), Dr. H. H. Dale, Sec. R.S. (Physiology), Dr. C. S. Myers, F.R.S. (Psychology), Prof. T. G. Hill (Botany), Sir C. Grant Robertson (Education), Sir John Russell, F.R.S. (Agriculture).

The addresses and discussions of direct interest to medical men will include the presidential addresses by Dr. Dale on the Biological Nature of Filtrable Viruses, and by Dr. Myers on the Nature of Mind; also the discussions on the physiological basis of sensation, biological experiments on man, resuscitation, social and industrial psychology, and the psychology of mental defect. The reception room will be at the Imperial Institute, South Kensington, and the sectional meetings will be held in various departments of the Imperial College of Science and Technology, at the Natural History and Victoria and Albert Museums, and at the house of the Royal Geographical Society at Kensington Gore. To mark the occasion of its centenary the Association is seeking to raise an endowment fund of £40,000. Contributions to the fund and all correspondence relating to the meeting should be addressed to the Secretary of the Association at Burlington House, London, W.

THE MECHANISED STUDENT.

Time was when the medical student, finding in his ward a new patient, sat by that patient's bed with a blank sheet of paper and wrote thereon such facts as seemed to him to be relevant out of the conversation they held. The subsequent criticisms of his chief taught him how to select and how to express what he had selected. In this country we have not got so very far from that to-day, but American methods of standardisation are creeping towards us, and those who have seen the immense dossier allotted to each patient in clinics run on the American method will be interested to hear that one of the originators of the systematised clinical record has already become alarmed at the growth of his own child. Dr. Eugene S. Kilgore[1] begs his countrymen to call a halt and make the technique of history-taking an intellectual rather than a mechanical process. Histories, he says, should exhibit uniform "clue-mindedness" rather than a uniform system of headings and paragraphs. He cites as an instance a Jewess, aged 45, whom he saw recently in a teaching hospital. Five minutes' conversation elicited the facts that her husband had died a year before, that she had then looked for support from her eldest son but had gradually realised that his talents were limited to the selling of newspapers, and she had therefore taken employment at washing dishes in a restaurant for eight hours a day, in addition to her home duties. She had the inevitable result: backache, insomnia, anorexia, exhaustion, and loss of weight. Her neat aluminium folder contained five and a half closely written pages of writing divided into 28 captions, all neatly underlined with red ink and ruler. The half-dozen really important items in her story were scattered far apart from each other under such headings as "soci condition," "occupation," and "marital history, with shortness of breath under "cardio-respirator system" and flatulence under "gastro-intestinal. Dr. Kilgore rightly declares that his student cou have made a better history before he ever set fo in a medical school. He suggests that the attem to amplify records for future statistical research should be abandoned in ordinary teaching hospital it would be enough if it were maintained for spec purposes in institutions where there is a reasona possibility that the data will be suitable for use a will be used. He suggests that students should taught to consider content rather than form and follow out significant clues with exhaustive thorou ness. They will not overlook any more importa data under the régime of free composition than th do under the régime of conventional paragraph British physicians have never cared for the mecha sation of their clinical scouts; they are likely remain content with the intelligent amplification four or five main headings.

VASCULAR PERISTALSIS.

Just before the war certain German physiologists claimed to have demonstrated electrical changes in arteries, which they held to be indicative of active contraction of the muscular coat. Blumenfeld, however, discredited this interpretation by showing that these changes in electrical potential could be explained on a purely physical basis as the result of the pulse-wave throwing a mass of blood against the wall of the vessel. R. M. Wilson,[2] on theoretical grounds and from a reconsideration of arterial pulse tracings, postulated an active arterial peristalsis. This view met with very little acceptance, and it is difficult to conceive of a peristaltic wave which could travel at the same rate as the pulse, while if it did not do so a pulse tracing should show two different and asynchronous waves. Now, however, A. Luisada[3] has reinvestigated the question from the aspect of changes in electrical potential along the course of the vessel. By means of high amplification he has been able to demonstrate diphasic followed by monophasic currents in the arteries of animals with each pulse-wave. He has repeated these observations on human subjects with the same results, and claims that these changes are evidence of muscular contraction, since control experiments on dead arteries and elastic tubes were absolutely negative. This work suggests that each pulse-wave is the stimulus to an active contraction of the arterial wall. In veins, also, he found electrical changes, but here of such large amplitude that it was possible to record them without amplification. The feature of these "venous electrograms" is the fact that the "contractions" are wholly irregular and cease after occlusion of the proximal end of the vein. Whatever may be the correct interpretation of these findings they form an interesting contribution to the discussion whether or not an active rôle should be ascribed to the arteries and veins.

SYMPATHETIC GANGLION LESIONS IN SCLERODERMA.

The ætiology of scleroderma is still much disputed, but facts are accumulating to support the view that implication of the sympathetic nervous system is associated with, or possibly the cause of, the disease. Geoffrey Blake describes a case[1] of a woman 30, who had attended hospital in 1919 for symptoms pointing to Raynaud's disease. This is not remarkable, since in the earlier stages of the sclerosing condition the extremities are often blue and cold, and the finger tips and nail beds may present atrophic changes. She was not seen again until 1923, when the skin changes had progressed and were recognised for what they really were, scleroderma with some degree of oderma, and the emaciation often associated with this condition. There were, in addition, symptoms relating to spasm of the œsophagus, confirmed by X ray examination. In July, 1929, X ray examination revealed obstruction at the pylorus, with dilatation of both the large and small intestines with almost complete obstruction of the descending colon. Ileosigmoidostomy was performed, but diarrhœa and vomiting were not relieved, and a cæcostomy was felt to be imperative. But the symptoms were not relieved, and the patient died on Sept. 22nd, 1929. At the autopsy, 12 hours later, sections were made of the skin and of portions of the endocrine glands. The changes due to scleroderma, which had been confirmed by a biopsy of the skin during the patient's lifetime, were again demonstrated. These included loss and atrophy of the papillæ, excessive pigment in the rete, dense sclerotic tissue in the dermis, with secondary atrophy of the cutaneous appendages. There were no definite microscopic abnormalities in any of the endocrine glands. The whole large intestine showed an abnormal degree of dilatation, which was so pronounced as to mask hypertrophy of moderate type. Of great interest and importance—especially if they are confirmed by reports on other autopsies—are the changes described in microscopic sections of the lower cervical sympathetic ganglion. The ganglion cells are said to be fewer than normal, many show striking changes. Some are enlarged and pale and show marked loss of finer structure; they appear to be "blown up." Others are small and shrunken, and stain deeply. Such changes have not been found in a series of controls taken at the same time after death. Other observers have sought in vain for such changes in the nervous system, although symptoms such as facial hemiatrophy and trophoneuroses, and the not-infrequent zonal distribution of sclerodermic plaques, would tend to support the association between scleroderma and lesions in the sympathetic nervous system. That Raynaud's syndrome is likely to be due to disease of this system would seem to follow from the results of arterial sympathectomy, and the clinical resemblances between scleroderma and Raynaud's disease in their early stages adds weight to the possibility of a common ætiology.

LEGUMINOUS CROPS AND MALARIA.

Prof. Hans Ziemann,[1] of Berlin, notes that under apparently similar physical conditions, and with similar mosquito prevalence, the amount of malaria may be surprisingly different. D'Herelle informs him that he noticed in the Argentine, 20 years ago, that leguminosæ grew about the streams and swamps in the malaria-free districts, but not in those where there was malaria. He observes that malaria disappeared from some islands of Holland in 1880, when clover from the south of France was sown there, and he agrees with Sir William Willcocks in ascribing the freedom of most of Egypt from malaria to the growth of wild clover, which is absent in the Suez canal zone, in Palestine, and in Greece, where the infection is prevalent. D'Herelle ascribes the influence of these leguminosæ to the coumarin contained in their blossoms, which appear in the malarial (summer and autumn) season. Ziemann also quotes Krysto, of the Russian Agricultural Department, writing in the *Scientific American* for April, who says that 35 years ago, when he lived in the Caucasus, everyone in his valley had malaria except the four who had planted beans and lucerne around their houses; he has seen the same in the Southern States and in Argentina, where malaria disappeared when lucerne was sown, though mosquitoes persisted as before. It is suggested that when the female mosquito sucks juice from these flowers she is either cured of her infection (as a man by quinine), or the gametes are sterilised. These questions have yet to be studied, and Prof. Ziemann calls for experiment. He gives a list of some 80 coumarin-containing plants and invites people living in a malarial district to choose those that will suit the climate, remembering they must flower throughout the worst season of infection.

SPEECH AND VOICE.[2]

In spite of numerous painstaking researches our knowledge of the exact mechanism by which the sounds of speech are produced is still very inexact. Especially is this the case for the production of the vowel-sounds which, although the variations of movement involved are probably very minute, are easily detected by the ear. The differences of voice quality present a similar problem; here personal quality and family resemblances are very definite, so as readily to be recognised even over the telephone, and probably depend on very small differences in the shape and structure of the producing cavities. Sir

[2] Speech and Voice, with X Rays of English, French, German, Italian, Spanish, Soprano, Tenor, and Baritone Subjects. By G. Oscar Russell, Ph.D., Director of Phonetics, Laboratories and Speech Clinic, Ohio State University. New York: The Macmillan Company. 1931. Pp. 250. 17s.

Richard Paget, whose work was reviewed in these columns a little over a year ago,[3] made extensive experiments with models to show that the vowel-sounds are musical tones of definite pitch, each associated with a pair of resonators formed by the throat and mouth. Mr. G. O. Russell does not believe that "cavity tone" supplies the entire solution of the problem, but thinks that the character of the surfaces and walls of the vocal cavities may be quite as important. He has evolved a method of showing the shape of the mouth and throat cavities, during speaking and singing, by means of X ray photographs, using a marker to fix the median sagittal plane. The technique is not exactly described, but a specially prepared thread is swallowed, which adheres to the mid-line of the tongue. It is difficult to see how the mid-line can be marked out in this way for other parts of the cavity. On the numerous pictures given in the text the cavities have been marked out in white, which makes them easier to read, but which also necessarily raises some little element of doubt. Mr. Russell also employs a "laryngoperiscope" of his own design, which enables the interior of the larynx to be examined during phonation, and he provides some interesting photographs taken by this means; a description and illustration of the instrument would be of interest. His X ray studies comprise over 400 subjects and 3000 experiments; this large mass of material has not yet been thoroughly digested, and the conclusions reached cannot be considered final. He believes that the X ray pictures of the mouth and throat positions during production of the different vowels will be of value, not only for the instruction of singers and in the pronunciation of foreign languages, but in the teaching of deaf-mutes.

THE B.M.A. AT EASTBOURNE.

THE members of the British Medical Association were fortunate in having three days of anticyclonic weather between two periods of rain and cold. The visitors, who took advantage of the many motor tours provided for them, saw Sussex at its very best—poppies, thistles, rampion, and cornflower blazed in the cultivated patches and a multitude of what Hudson called the "fairy flora of the downs" chequered the "wise turf" of Beachy Head and the Seven Sisters. Brilliant sunshine favoured the Civic Garden-party in the beautiful grounds of Folkington Manor on Thursday afternoon, and Devonshire Park provided a handsome setting for the evening receptions. Over 1100 members and guests attended the President's reception on Tuesday evening, and nearly as many were to be seen at the Civic Receptions on the two subsequent evenings and at the Marquess of Hartington's ball on Friday night. The annual general meeting was held in the Town Hall, where members robed for the procession to St. Saviour's Church for the official religious service. The sermon was preached by the Bishop of Chichester, and the service was preceded by a brief ceremony of remembrance at the war memorial. An attraction to many visitors was the county cricket match, Somerset *v.* Sussex, which was conveniently timed to take place on the three days of the meeting, while golf competitions and tennis tournaments were available for the strenuous. Medical missionary, and temperance breakfasts were held as usual, and, in addition, a Rotary luncheon, an Irish graduates' luncheon, a Masonic meeting, and a secretaries' dinner claimed attendance from those suitably qualified. The popular lecture was delivered by Prof. F. T. G. Hobday on Some Diseases of Animals Communicable to Man. The lecturer laid special stress on the regrettable existence of tuberculous milk and the chaotic state of the present regulations governing milk-production and sale in this country. Some interesting films were shown. The first was a record of the Canadian meeting last year; the second was a "talkie" depicting lower segment Cæsarean section as performed under local anæsthesia by Dr. J. B. De Lee at the Chicago Lying-In Hospital. Dr. R. G. Canti showed to enthusiastic audiences his latest moving pictures of microscopic life, and Petrolagar Laboratories showed a series of films illustrating intestinal movements in animals. A party of 100 people was entertained to a tour of the Level, dinner, and a concert by th Hastings Division and Corporation on T afternoon and evening, and other parties neighbouring medical institutions.

RIVER POLLUTION—THE TEES SURV

How is it that some rivers manage of the to purify the polluting liquids they receive? quantities of different effluents can these rivers with without destroying the conditions of purification? Faced with such questions as the Water Pollution Research Board dec examine a typical river flowing through an ind area. It chose the Tees, which, in the 12 miles b Stockton and the sea, takes not only the effl many factories, but also the untreated sew Thornaby, Stockton, Middlesbrough, and Pillin. A Tees Survey Committee began work in April, and the first instalment of information is now lished.[1] It deals with the hydrography of the river; complementary studies of the biological chemical aspects will take another three years complete. Meanwhile the Ministry of Agricul and Fisheries is examining the non-tidal reaches.

One important result of the hydrographical sur is our definite knowledge of the movement of curr at different depths. At most of the observing statio the flood was found to run strongest at a depth bel 1 fathom; the ebb, without exception, was strong on the surface. From the surface to a depth 1 fathom the current ebbs longer than it floods. Belo 2 fathoms the flood runs for 6½ hours or longer, and t ebb is less than 6 hours. The maximum speed of t flood is at 1 or 2 fathoms' depth, and not at t bottom, where friction against the river-bed reta the flow. We have to reckon with the different dens of fresh and salt water. We find the flood runni up-stream in the deeper layers, while the ebb is st running out on the surface. Thus the broad inferen appears that polluted matter will not readily esca seawards unless it is in the surface layer. It important, therefore, though apparently not eas to obtain accurate measurements of the thickness the upper layer. Useful evidence of silting, explicab with better knowledge of the depth of the river-be and the strength of the current, is available from th experience of the Tees Conservancy dredging opera tions. Indeed, the coöperation of local interests in th survey is a hopeful sign. When all the results of th inquiry are published and coördinated, there shoul be much to learn. In a preface to the report of th hydrographical survey, Mr. H. T. Calvert, D.Sc., th

Director of Water Pollution Research, can fairly claim that this pioneer work, with its apparatus of tables and diagrams, will be a useful precedent and pattern for similar investigations elsewhere.

LORD KNUTSFORD.

THE announcement of the death last Monday of Lord Knutsford has been received with deep regret by the medical profession, who recognised in him a life-long and tireless worker in the cause of the sick poor. A pioneer in the service of the voluntary hospitals, who lived to be a veteran in that service, his enthusiasm never faltered, his courage never wavered, and his dogmatism had the justification of unrivalled experience. Forty years ago, when a director of a London dock company, he visited an injured labourer in the Poplar Hospital, and the sequel of his errand of mercy forms an apt illustration of his character. His senses having convinced him that the building was obsolete and the management deplorable, he took immediate charge, unsupported by the managing committee, raised the money urgently required to render the structure sanitary, started new buildings, and a new administration.

LORD KNUTSFORD.
[Photograph by G. C. Beresford

His practical success in the smaller place led to an invitation which 30 years ago brought him to the assistance of the London Hospital. He was placed on the committee of management, and submitted, almost on the spot, to that body a report on the existing condition of affairs, with the result that the sitting chairman resigned and Sydney Holland, as he then was, took his place with the avowed object of introducing drastic reforms. What has happened to the institution during the last 30 years is known to everyone. Great things were done and great men adorned the staff of the hospital before the era of change, but the work was carried on in conditions that to-day would seem incredible, and even at the time were recognised as faulty. The growing need for laboratories had not been met; operating surgeons were hampered by lack of facilities at the very time when the discoveries of Lister were making the fields of operation almost infinitely larger; while accommodation for nurses was almost absent. To-day, under Lord Knutsford's chairmanship, the hospital, while housing some 30 per cent. more patients, is a model centre of healing in all its branches, is fully furnished with laboratories, has a fine college affiliated to it, and a famous training institution for nurses. The vast expenditure of public money thus implied was made possible by Lord Knutsford's extraordinary power of extracting money. In his numerous appeals he was forcible, pathetic, and witty by turns, or a very effective blend of all three. While he argued or persuaded with recurring success large groups of the public to aid the London Hospital, he was also particularly fortunate in his attacks upon individual purses. This was well revealed in an amusing book, "The Prince of Beggars," written by one of his former private secretaries, in which Lord Knutsford's methods of securing subscriptions and donations to "the London" were recorded.

Lord Knutsford had made a particular study of the nursing question, and had been successful in introducing drastic reforms at the London Hospital. Inevitably he found it difficult to believe, without statistical evidence, that a shortage of candidates could exist sufficient to justify the setting up of a commission of inquiry by THE LANCET. He narrated his views on the subject to the Editor of THE LANCET in frank letters and in more than one conversation. At his own institution, he said, there was no shortage of nurses and no criticism of the conditions of service in hospitals had reached him. It was characteristic of him that, although he remained unconvinced of any need for the inquiry, he gave us his personal assistance in supplying answers to the questionaire, the document being preceded by an ironical blessing of his friend, the chairman, and the statement that it had taken more than five hours to fill up.

While work at "the London" employed most of Lord Knutsford's time and energy, he was always to be found as a public champion in the cause of progressive medicine, as was fitting in the grandson of that great physician Henry Holland. He took many opportunities in the House of Lords of recording the debt owed by humanity to the scientific discoveries of medicine, and one of his last public appearances must have been at the annual meeting of the Research Defence Society over which he presided. Not only the voluntary hospitals but all those connected with the advance of medicine will mourn his loss, while men and women placed in every status of society will feel the loss of his genial and forceful friendship.

CHEMICAL SPERMICIDES.

THE July number of the *Journal of Hygiene* contains the third of a series of papers by Mr. J. R. Baker, D.Phil., in which he reports on a long programme of experiments[1] upon the spermicidal power of chemical contraceptives conducted by him in the department of zoology and comparative anatomy at Oxford. These experiments are not yet complete, and it would be premature to regard any of the findings so far published as affording guidance as to which chemical substance or which proprietary product is most satisfactory from the clinical point of view. At the same time there is good reason for supposing that when the series of tests is complete there will be placed at the disposal of the medical profession a spermicidal pessary considerably more effective than any now in use.

The present paper describes a careful comparison of the effects upon guinea-pig and human sperm of several of the contraceptive suppositories and foaming tablets now on the market. An attempt is made to evaluate the relative spermicidal rôles of the foaming substances contained in these articles as against the ingredients which act by purely chemical means. It is further shown that the cocoa-butter base, in which quinine and chinosol are often incorporated, exerts a neutralising effect upon these substances. Thus grs. 5 (0·324 g.) of finely powdered quinine bisulphate or grs. 3 (0·195 g.) of chinosol, which are the quantities contained in a vaginal pessary, will completely immobilise spermatozoa in a quarter of an hour. The same quantities of the same substances, when incorporated in a cocoa-butter base, have no appreciable effect in a much longer period. From these results, however, it is not to be concluded that the contraceptive value of pessaries, consisting of quinine or chinosol in cocoa-butter, is negligible. There is now available in unanalysed form a considerable body of evidence that many women have successfully spaced their pregnancies by using these pessaries alone. There is therefore a strong implication that the cocoa-butter may exert a contraceptive effect by covering the cervix with a thin film which impedes the ingress of spermatozoa. This mechanical action is acknowledged as an important clinical factor by Dr. Baker, who clearly realises that his experiments take no account of it.

---

[1] See also THE LANCET, 1930, i., 366.

Research in the direction of improving contraceptive methods may take two directions. In the first place, it is necessary to ascertain the comparative contraceptive value of different vehicles, whose action is purely mechanical; in the second place the comparative spermicidal power of chemical substances must be determined. Dr. Baker's investigation of the second group of problems has already exploded a highly misleading fallacy. He has shown that the assumption made by certain manufacturers that because a substance is a good germicide it is also a good spermicide is erroneous. Thus, sodium dichlorylsulphamidbenzoate, the chief ingredient of one of the most widely advertised foaming tablets, was found by him to have the lowest spermicidal power of any of the chemical substances he has examined. When the parallel investigations of vehicles and spermicides are complete, it will be necessary to combine the most effective of these in such a way that the chemical activity of the spermicide is little or not at all impaired by the vehicle. The next step will be to ascertain the minimum concentration of the spermicide which is capable of producing vaginal or uterine injury in animals; and, if possible, to assure ourselves that the combination cannot damage the sperm in such a way as to lead to the production of defective individuals in later generations. These researches are now being carried out.

THE LIGHTING OF SCHOOLS AND LIBRARIES.

THE Council of the Illuminating Engineering Society has published the reports of three subcommittees dealing with the lighting of schools and libraries.[1] A report on library lighting was published in the *Illuminating Engineer* for July 13th, 1913, and the present report brings that up to date. The chief requirements of a library are sufficient illumination, together with the avoidance of dazzle, glare, and shadow. The ceilings and walls should be finished in a light colour, as they then add diffused light, and soften shadows and contrasts. Polished and glossy surfaces should be avoided. No unshaded lamp-filament or gas-mantle should be visible at any angle to persons reading at the tables, and the shades on stand lamps or table lamps should be opaque or of very low surface brightness. For general illumination of the room the lighting should be not less than one foot-candle and the illumination on the tables from all sources not less than five foot-candles. If supplementary lighting is needed for newspaper stands, it is conveniently supplied by tubular lamps in trough reflectors, slightly above and about a foot in front of the top line of the stand, giving a well-diffused source of light.

The first report on the lighting of schools is a revision of that issued in the same journal in July, 1914, and deals with daylight. It takes as the minimum standard of adequate light for ordinary purposes 0·4 per cent. sill-ratio or 0·2 per cent. daylight-factor. It recommends that every child should have a view of the sky from its desk and that the area of sky visible should be sufficient to afford an illumination on a horizontal plane at desk or table height equivalent to a daylight factor of 0·5 per cent. of the illumination from a complete hemisphere of sky, all parts of which are equally bright. Windows should preferably be on the left of the pupils, and any windows on the right should be designed for cross ventilation only, or for the admission of sunlight to the room when pupils are out. Roof lighting is undesirable, and windows facing the pupil are highly objectionable. Window-heads should be horizontal, and the glass should be carried up unobstructed if possible to ceiling level. The ceiling should be white, and the walls light in colour, while desks and furniture should be light and unobtrusive.

Another committee reports on the artificial lighting of schools,[2] and recommends that the illumination of desks and tables should be five foot-candles fo ordinary work and eight foot-candles for special work. For assembly and recreation rooms three foot-candle is considered sufficient, and the general illuminatio should nowhere be less than one foot-candle. O blackboards the light should be 60 per cent. in exces of that on desks or tables. Great importance i attached to the avoidance of glare, and it is recommended that no incandescent or bright reflecti surface should be visible to the eyes of teacher o pupils at work and no source of light—unl completely screened—should be below a line dra from a point on the back wall 3 ft. 6 in. above th floor to a point 4 ft. above the upper edge of th blackboard surface. Blackboards should be mai tained in a dark and matt condition, and books shou be printed, as far as possible, on matt pap Objectionable shadows are to be avoided by obtain light from diffusing media and keeping the walls a ceilings light. Lights on stairways must be place that each flight is illuminated from above and bel and shadows of risers on the treads are avoided. classrooms four lamps not less than 10 ft. above t desks are convenient, but additional units may necessary for the blackboard and the teacher.

MEDICAL RESEARCH COUNCIL.

Lord Dawson of Penn, President of the Roya College of Physicians of London, and Dr. Edwar Mellanby, F.R.S., professor of pharmacology in the University of Sheffield, have been appointed member of the Medical Research Council in succession to Prof. T. R. Elliott and Prof. J. B. Leathes, who retire in rotation on Sept. 30th.

INDEX TO "THE LANCET,"
VOL. I., 1931.

THE Index and Title-page to Vol. I., 1931, which was completed with the issue of June 27th, is now ready. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 7, Adam-street, Adelphi, W.C.2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

---

[1] Copies can be obtained on application to the Hon. Secretary, Mr. J. S. Dow, 32, Victoria-street, S.W.1.

SPECIAL ARTICLES

THE PROGRESS OF WORK ON CALMETTE'S B·C G VACCINE.

CALMETTE has given a general review of the progress of B C G work in France and in other countries in his report to the Seventh International Conference against Tuberculosis, held at Oslo, 1930.[1] At a meeting of the Section for the Study of Disease in Children of the Royal Society of Medicine, held on June 9th, 1931, he described the experimental and clinical results which he had obtained (vide *The Lancet*, 1931, i., 1298, and the *British Medical Journal*, 1931, i., 1070).

The number of infants immunised with B C G in France during the period July 1st, 1924, to May 1st, 1931, a period of over 5½ years, exceeds 336,000, and there are now more than a million vaccinated children in the world. Calmette states that between the age of one month and the end of the fourth year the mortality in France from tuberculosis of children born of tuberculous mothers or brought up in a tuberculous environment, is 15·9 per cent., while it is only 3·4 per cent. for children in this age-period who have been vaccinated with B C G. The treatment is not designed to produce a permanent immunity, but to give sufficient resistance to the child to carry it through a dangerous period of life and to enable it to go through the usual course of natural immunisation to tuberculosis by repeated small infections without the risk of such infections becoming progressive. In other words, the immunising value of B C G is transient.

Calmette and his associates are emphatic that [illegible] is an efficacious prophylactic agent against tuberculosis, and that its use is innocuous. They do not deny that the organism is capable of producing lesions in the animal body, but they claim that such lesions are entirely benign and incapable of developing into active centres of tuberculosis. It has been further shown that B C G can be recovered from these lesions, but is still incapable of setting up a progressive tuberculous infection on reinoculation into fresh animals. These contentions and experiments have been supported by other observers. Lange and Clauberg[2] find B C G innocuous in guinea-pigs, and Kühn[3] and Okell and Parish[4] could neither produce generalised lesions nor raise its virulence. Similar observations have been made by Jensen, Morch, and Orskov,[5] and Remlinger and Bailly,[6] King and Park[7] find that B C G gives an appreciable immunity in guinea-pigs and Wilbert[8] and Gerlach and Kraus[9] find it of immunising value in monkeys. Webb[10] considers it should be administered to infants born of parents with open tuberculosis. Similar views in regard to the value of B C G in protecting children from tuberculosis have been expressed by Bernard,[11] Giraud,[12] Blanc,[13] Keller,[14] Malvoz and Van Beneden,[15] Moine,[16] Ott,[17] Rougebief,[18] and Weill-Halle and Turpin.[19]

Criticisms of BCG.

The observations of many other investigators raise doubts as to the innocuity and immunising value of B C G. Watson,[20] who has made prolonged observations on guinea-pigs, rabbits, and cattle, feels "fully warranted in considering B C G vaccination as in the experimental stage, and, in respect to its innocuity and efficiency, open to question." Larson and Evans,[21] Schroeder and Crawford,[22] Korschun and Dwijkoff,[23] and Uhlenhuth, Müller, and Hillenbrandt[24] find it of no value in cattle. Petroff[25] and others have found that guinea-pigs vaccinated with B C G were not protected against a subsequent experimental infection. Nohlen[26] had similar results in monkeys and Schlossmann's experiments[27] on monkeys offer him but little hope that Calmette's aim to eradicate tuberculosis by prophylactic immunisation has been achieved. Armengol,[28] Chiari, Nobel, and Sole,[29] Galli-Valeria,[30] Hutyra,[31] Moti Malkani,[32] Petroff, Branch, and Steenken[33] noticed that some of their animals died of tuberculosis after B C G inoculation, and that the virulence of B C G could be raised by animal passage. Lignières[34] does not regard B C G as harmless, and is of opinion that it confers only a transient immunity. Loewenstein[35] observes that an organism which is not virulent for the guinea-pig may be gravely pathogenic for man, and that its virulence may increase, especially in the young. Calmette's contention that if B C G is ingested during the first ten days of life enough of it would be absorbed to protect against a subsequent exogenous infection has been severely criticised on experimental grounds by Petroff[25] and others. Wallgren,[36] from his experiences in children, finds that the amount of B C G absorbed by an oral route is uncertain, and that a tuberculin reaction is the only evidence that vaccination has taken place.

Clinical observations and fatalities amongst B C G-vaccinated children have been reported by Baigue,[37] Chenard and Ferrier,[38] Girod and Debarge,[39] Heynsius van den Burgh,[40] Munoverro,[41] Nobecourt,[42] Pirquet,[43] Saye, Domingo, and Miralbell,[44] Taillens,[45] and Weill-Halle and Turpin.[19] These findings are not in accord with the entirely favourable reports which Calmette publishes from time to time regarding the innocuity and efficiency of B C G in children.[46]

Investigations in Great Britain.

Shortly after the publication of Calmette's early results, a special committee was set up by the Medical Research Council in close accord with the Ministry of Health to investigate the question of B C G. The committee desired in the first place to examine the work on B C G from the statistical and bacteriological standpoints before entering upon any clinical investigation. The statistical inquiries of Prof. Major Greenwood, F.R.S.,[47] of Wolff, in Germany, and of Rosenfeld, in Austria, have been critical of the figures quoted by Calmette, and others in favour of the B C G results. Their criticism falls under two heads. It deals with Calmette's figures on technical statistical grounds, and in the second place it draws attention to the inherent dangers of fallacy residing in the fact that infants receiving *any* special prophylactic treatment are likely to be given, consciously or unconsciously, better guardianship of many kinds than they would otherwise have received.

The experiments of Dreyer and Vollum[48] tend to show that under conditions of cultivation in a fluid medium B C G cultures can regain their former virulence. Stanley Griffith,[49] working for the Tuberculosis Committee of the Medical Research Council, shows that B C G produces little or no immunising effect in the monkey against subsequent tuberculous infection. His conclusions are as follows:—

(1) The strain of B C G used in these experiments can produce local lesions in the rhesus monkey, but these are always benign and do not lead to generalisation.

(2) B C G given by the mouth can pass through the mucous membrane of the alimentary canal into the adjacent glands and also gain access to the blood stream.

(3) Vaccination with B C G, whether by feeding or by injection, has failed to give to monkeys the complete protection against tuberculosis reported by Wilbert, but in some instances may have produced a low grade of relative immunity.

The preliminary results obtained by J. B. Buxton and Stanley Griffith[49] with calves are more encouraging.

The authors arrive at the following conclusions:—

(1) The strain of B C G used throughout these experiments would appear to be avirulent for the calf and incapable of giving rise to progressive tuberculosis even when inoculated in large doses.

(2) Whether given by the mouth or intratracheally, or by subcutaneous or intravenous injection, B C G can raise the resistance of a calf to a virulent experimental infection.

(3) An increase of resistance is less certain after feeding with B C G than after intravenous injection, though feeding with the vaccine may in some instances induce as high a resistance as injection into the tissues.

(4) Intravenous injection has proved the most satisfactory method of vaccination with B C G.

(5) The degree of increased resistance conferred upon calves by intravenous vaccination varies within wide limits, and appears in general to be directly proportionate to the dose of B C G vaccine.

The experiments were, in the first instance, concerned with questions of the best method of administration and dosage of B C G. The tests of resistance were made therefore after an interval when one might suppose that the resistance was at its highest level—that is, from two and a half to three months from the beginning of the vaccination. In future work the authors propose (*a*) to ascertain the duration of the increased resistance produced by intravenous vaccination; (*b*) to test the resistance of intravenously vaccinated calves against a natural mode of infection; (*c*) to compare the resistance produced by other antigens.

It will be recalled that Petroff[33] differentiated "rough" and "smooth" colonies in cultures of B C G. He found the smooth colonies were virulent, the rough colonies avirulent. In a recent paper R. S. Begbie[50] reported that he had obtained three types of colony from a culture of B C G—namely, "smooth," "rough," and "intermediate." Experiments on guinea-pigs did not show clear-cut lines of demarcation in the virulence of the types of growth obtained, but definite variation was noted, the "smooth" type being most virulent, the "rough" type intermediate in virulence, and the umbilicated or "intermediate" type of growth the least virulent. Begbie concludes that variants from B C G are capable of producing death from tuberculosis when inoculated into guinea-pigs, and therefore the suitability of B C G for immunisation of infants against tuberculosis must still remain open to question.

The Catastrophe at Lübeck.

During the period Feb. 24th to April 25th, 1930, 251 infants within the first ten days of life were given B C G vaccine by mouth in Lübeck. The vaccine was prepared from a culture obtained from the Pasteur Institute in Paris, and was issued from Prof. Deycke's laboratory. Some of the vaccine was administered by Prof. Deycke and his assistant, but most was entrusted to the midwives in attendance upon the births to give. According to Bruno Lange,[51] up to Oct. 18th, 1930, 74 of these children died, but seven of the deaths were not attributed to tuberculosis. Sixty-seven of the deaths were due to tuberculosis. The lesions extensively involved the glandular system, especially the mesenteric glands, and extended to the tracheobronchial glands and the lungs. The cultures obtained from the lesions proved to be those of a virulent human type of tubercle bacillus, which Bruno Lange has identified with a culture which was sent out by the Robert Koch Institute to the Kiel Laboratory, and which was sent to Lübeck at the request of Prof. Deycke in October, 1929.

Immediately, on the news of the catastrophe, Prof. G. Dreyer, F.R.S., and Captain S. R. Douglas, F.R.S., visited Lübeck on behalf of the Medical Research Council. They made a confidential report to the Tuberculosis Committee of the Medical Research Council in which they described the pathological lesions, but suspended judgment as to the cause of the fatalities pending an investigation by the German Imperial Health Council.

The report of the chief member of the Government Board, Prof. Ludwig Lange, to which have been added the statements of Prof. Neufeld (Berlin) and Dr. Kirchner (Hamburg), caused the German Imperial Health Council at its sittings on Dec. 12th and 13th, 1930, to arrive at the following conclusions regarding the fatalities at Lübeck. The illness and deaths of the infants were not traceable to the original B C G cultures, but were probably due to some unexplained admixture with virulent tubercle bacilli. The Imperial Council have also confirmed their decision of 1927 that the use of living bacilli, even in an attentuated form for human prophylaxis is undesirable in the present state of knowledge. Calmette has drawn specia attention to the exoneration of B C G in the Lübeck disaster.[52]

Conclusion.

This review of the progress of work on B C G wi account for the conservative attitude in Great Britai towards the use of the vaccine. Observations o the subject made at the Seventeenth Annual Congres of the National Association for the Prevention o Tuberculosis this year indicate that at present B C is still regarded as being in the experimental stag While uncertainty still persists as to whether the livin vaccine, B C G, is free from virulence under conditions and doubt is expressed as to its effec immunising properties, its use as an immunising agen particularly for young children, is unlikely to b advocated in this country on any extensive scale.

THE SECOND INTERNATIONAL ORTHODONTIC CONGRESS.

THIS Congress was held at the Savoy Hotel, London, from July 20th to 24th, under the presidency of Mr. J. H. Badcock. Over 20 countries were represented, the total membership being over 400. The Congress was opened by the Mayor of Westminster, who welcomed the members to the historic city of Westminster. A letter was read from the Minister of Health, who regarded the selection of London in succession to New York as the meeting place of the second Congress as a tribute to the contributions to orthodontics by the President-General and others in this country.

After the Honorary Presidents from abroad had been welcomed by the President-General, the latter, in the course of his

PRESIDENTIAL ADDRESS,

said that orthodontics was the science and art connected with the causes and treatment of malformations of the jaws and irregularities of the teeth. It was important from the social, economic, and hygienic standpoints. An unsightly irregularity of the teeth might be the cause of an inferiority complex. It might be prejudicial to health in various ways by leading to caries and pyorrhœa. Malocclusion of the teeth was a concomitant of civilisation, and it was probably true that the more artificial the conditions under which a race lived the greater would be the percentage of persons affected with malocclusion. Malocclusion was not limited to the human race, for, according to Sir Frank Colyer, every form of irregularity might have its counterpart in the lower animals. The President suggested that a possible cause for the occurrence of malocclusion in man and animals might be deficient diet, leading to defective bone growth. The possibility of sexual selection should not be overlooked, for the somewhat narrow upper jaw, with the teeth just in evidence, and the dimple in the chin associated with mild cases of distal occlusion, undoubtedly had its attractions. Mr. Badcock paid a tribute to the earlier workers on the subject, such as John Hunter and Duval. He said that the profession owed much to the late Dr. E. H. Angle, who gave a new trend to orthodontic thought and practice. A vote of thanks to the President-General was proposed by Dr. Grieve, and carried with acclamation.

SCIENTIFIC PROCEEDINGS.

Mr. H. F. Humphreys (Birmingham) discussed the changes in the temporo-mandibular joint and its bearing on orthodontics, especially in relation to the treatment of post-normal occlusion. Dr. G.W. Grieve (Toronto), in a paper on Orthodontic Diagnosis, advocated strongly the claims of extraction in treatment, and said that many cases treated by expansion of the jaw only relapsed. Mr. H. Chapman (London) also read a paper on Extraction as a Part of Treatment, in which he gave reasons why extraction was often advisable and led to better results than the retention of all teeth. Both these papers received considerable discussion. In the absence of Prof. Simon, of Berlin, his important paper on the Practical Value of the Biometrical Norm in Orthodontics was taken as read. Dr. Martin Schwarz (Vienna) described experiments on dogs, in which the teeth were moved by means of appliances and the bone examined microscopically after the animals had been killed. The results had led him to the conclusion that the findings of Oppenheim, which were based on similar experiments and had long been accepted, were wrong.

Mr. G. G. and Mr. D. H. Campion read a joint paper on Facial Measurements in Diagnosis, in which they described investigations carried out over several years for the Dental Committee of the Medical Research Council. A paper on the Growth Changes of the Teeth and Dental Arches, by Mr. S. J. Lewis, Mr. I. Lehman, and Mr. M. Mumblatt, of Detroit, evoked a keen discussion. An interesting paper on Oversized Tongues as a Cause of Malocclusion was read by Dr. F. Neumann (Prague), who described several cases of irregularities of the teeth apparently caused by large tongues. Mr. V. H. Kazanjian (Harvard) gave an account of five cases of inferior protrusion treated surgically by resection of the mandible with excellent results. The Local Factors in the Ætiology of Malocclusion were dealt with exhaustively by Dr. Axel Lundström (Stockholm). The Changes in the Teeth and Jaws in Acromegaly were discussed by G. Korkhaus (Bonn). The place of Orthodontics in Dental Education was discussed by Leroy Miner (Boston) and C. Nord (Holland).

SOCIAL FUNCTIONS.

A banquet was held at the Savoy Hotel on July 23rd, the President-General being in the chair. More than 200 members and guests attended. After the toast of "The King," proposed by the President-General, a presentation of golf trophies was made, and the toast of the evening, which included in its terms "The Nationalities Represented," was proposed by Mr. T. Watts Eden, president of the Royal Society of Medicine. He offered greetings from this society. It had been said that deterioration of the teeth began in man when he first began to cook his food. No progress in preventive measures, he said, would be made until the cause of dental defects was found and explained to the people, and their sympathies enlisted. The dentist had succeeded in thus gaining the confidence of the people in preventive measures, for they visited him regularly to see if all was well with their teeth. It was rare indeed for anybody to go regularly to his doctor to see if he was sound in body and mind. A great responsibility lay upon the orthodontist in blazing the trail of prevention. He coupled with the toast the names of Dr. E. T. Bennett (Australia), Dr. Casto (U.S.A.), Dr. Brufau (Argentine), Dr. de Coster (Belgium), Dr. G. W. Grieve (Canada), Dr. Eduardo Ferraro (Chile), Dr. F. Neumann (Czechoslovakia), Mr. A. T. Pitts (Great Britain), Dr. J. Quintero (France), Dr. Körbitz (Germany), Dr. Nord (Holland), Dr. Rehák (Hungary), Mr. Friel (Irish Free State), Dr. d'Alise (Italy), Dr. Hisasho Saito (Japan), Dr. A. Puljo (Jugoslavia), Dr. R. Salazar (Peru), Mr. W. Floyd (South Africa), Dr. A. Lundström (Sweden), Dr. R. Schwarz (Switzerland), Dr. Habib Rihan (Syria), and a representative of Austria. Each of the members toasted having replied, Dr. C. A. Spahn, the Vice-President-General, gave the toast of "The Guests," and expressed the satisfaction of the members of the Congress at the presence of the Mayor and Mayoress of Westminster. He coupled with the toast the name of Prof. G. Elliot Smith, F.R.S., who had delivered an address to the Congress on evolutionary tendencies in teeth and jaws (see THE LANCET, July 25th, p. 199). Prof. Elliot Smith expressed on behalf of the guests their appreciation of the generous hospitality shown to them.

A reception to the members of the Congress was given by the President and Council of the Royal College of Surgeons. The guests were welcomed by Sir Holburt Waring and Mr. Sampson Handley, in the absence of Lord Moynihan. An address on Deformities and Fashion was given by Sir Arthur Keith, and the Odontological Museum was described by the Curator, Sir Frank Colyer.

(FROM OUR OWN CORRESPONDENTS.)

HOSPITALS AND THE LOCAL AUTHORITIES.

THE undertaking by various hospitals to carry out for local authorities the treatment advised by school medical inspectors is causing embarrassing situations. When the various arrangements were made it does not seem that due attention was paid to the propriety of an income limit being imposed as regards those who were to obtain treatment at the special rates. It has happened, therefore, that although the local authority is able to recover the cost of treatment of school-children in cases where the parents are well-to-do, the hospitals receive the same payment as in the case of the poor, while the medical staffs receive either no fee or a merely nominal fee. In many cases the children treated are of a class which could, and should, pay for treatment at ordinary professional rates, and their treatment in a public or charitable hospital is an abuse of the functions of such an institution.

A difference of opinion of some importance in this respect has arisen in Cork. It appears that the Cork district hospital has for some time been carrying out the treatment of children sent by the school medical officers of the city, under a scheme arranged between the hospital authorities and its medical staff. In this scheme an income limit of £4 a week for parents of the children to be treated had been agreed on, and so far no difficulty had arisen. Recently, however, it was proposed to treat children from the county of Cork under a similar scheme, but the members of the medical staff found themselves unable to agree to as high an income limit for country patients as for city patients. As a result Dr. G. A. Barter, who is ophthalmic surgeon to the Cork district hospital, has refused to treat well-to-do patients *from the country as part of his duty.* The Department of Local Government and Public Health thereupo instructed the South Cork board of public assistance (the authority in charge of the district hospital) to call for Dr. Barter's resignation, and the board has passed a resolution to that effect.

The legality of any attempt to dismiss a medic officer for refusing to perform duties not contemplated in the terms of appointment is questione but, apart from the legal point, it is clear that th whole issue raised requires more serious consideratio than it has received. The hasty action of the Depar ment of Local Government and Public Health specially unfortunate, and is in contrast with usual habit of prudent deliberation.

THE HOSPITALS AND THE SWEEPSTAKES.

The Governors of the Rotunda Hospital, aft much deliberation and by a majority, have decid to apply for a share in the next sweepstake. One m assume that the governors do not like sweepstak as a method of financing hospitals, or they wo long ago have applied for participation. Their act now is almost under the compulsion of necess The hospitals which have hitherto participated, well as those which have hitherto stood out, coming to realise that the old method of finan hospitals by voluntary subscriptions is obsolesce if not obsolete. The well-to-do, when asked, subscribe, have a ready answer. If the appeal is behalf of a hospital which has benefited by sweepstakes, the answer is, "You do not need furt help." On the other hand, if the appeal is on beh of a hospital which has not participated, the ans is, "Go into the sweepstakes and you will h plenty!" In neither case is the answer a true o but it serves. Whether the voluntary system d of itself, or was killed by the sweepstakes, is a matte not easy to decide. A practical problem remai nevertheless. The sweepstakes cannot be more th a temporary expedient. What is going to be th means of future support of the hospitals? Those wh introduced the sweepstakes claimed that they wer preserving the voluntary system, and avoiding the necessity for State support and State control. It looks *now* as if they were providing the bridge between the voluntary system and nationalisation.

TESTIMONIAL TO PROF. THOMAS SINCLAIR.

A number of friends, colleagues, and pupils of Colonel Thomas Sinclair, emeritus professor of surgery in the Queen's University of Belfast, have thought it appropriate that some public recognition should be made of the distinguished services which he has rendered to that University and to the Belfast Medical School. Prof. Sinclair became professor of surgery in 1886, and occupied that chair for 37 years. He may justly be regarded as the founder of modern surgery in Ulster. Since his resignation in 1923 he has represented the University in the Imperial Parliament, and has acted as registrar and pro-chancellor of the University. He has also served as a member of the Senate in the Parliament of Northern Ireland. It has been found impossible to notify personally all the former students of Prof. Sinclair, many of whom, doubtless, would wish to share in this testimonial. Subscriptions (maximum 2 guineas) will be received by the Rt. Hon. Samuel Cunningham, 3. Donegall Square East, Belfast.

RESIDENT MEDICAL OFFICER IN A PUBLIC SCHOOL.

The governors of the Campbell College, Belfast, are to be congratulated on being the first board of any public school in Ireland to appoint a whole-time resident medical officer to look after the health of the boarders and day boys, and the hygiene of the school. Dr. Jenkins, who has been selected from many applicants, is a former captain of the St. Bartholomew's Rugby football team, and played also for the United Hospitals and Middlesex County. He has also for a period had experience of medical school work at Rugby.

Old Campbellians will regret the retirement of Mr. R. W. Leslie as medical officer to the school, a post he held for 35 years. He attended medically many of the fathers, when boys at Campbell, who have now sons at the school.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

A CHAIR OF CHILD LIFE AND HEALTH.

THE Edinburgh University court have appointed Charles McNeil to the Edward Clark chair of ild life and health. The establishment of this w chair has been generally welcomed and the new fessor comes to it with a fine record. He took up special study of children with the late Dr. John omson and succeeded him as senior physician to Royal Hospital for Sick Children. He is also iversity lecturer on diseases of childhood. During war he was in charge of the Scottish Hospital at uen from October, 1915.

E ROYAL COLLEGE OF PHYSICIANS' LABORATORY.

At the last quarterly meeting of the Royal College Physicians of Edinburgh, Sir Robert Philip, urator of the laboratory, was able to present a aluable report on the work of the past year. ieut.-Colonel A. G. McKendrick, the superintendent, nd 18 fellow-workers, have been engaged in 23 investigations of pathological, bacteriological, chemical, nd mathematical problems. In their studies of pidemics Colonel McKendrick and Mr. Kermack deal with the fluctuations superimposed on endemic disease by an influx of fresh individuals by birth or immigration at a constant rate. They have also analysed the epidemiology of kala-azar on data submitted from India. They find that the chance of a household becoming infected increases with the number of its members, but that individual chances of infection are *less* in larger households than in small ones. They have aimed at obtaining a quantitative relation between the chance of an individual becoming infected and the size of the household. The results are consistent with the theory that kala-azar is spread by the sand-fly, but need further investigation. The superintendent has also published a statistical review of antirabic treatment, the work being undertaken at the instance of the Health Section of the League of Nations.

In an investigation of cancer of the breast, carried out in association with the late Prof. J. Lorrain Smith, Mrs. Dawson has made an extended histological study of the normal breast during various phases of growth and activity. The malignant process does not appear to originate in the fully developed epithelial cells lining the acini of lactation. but usually in the epithelium of the small terminal ducts from which secreting acinar epithelium is itself derived. Lieut.-Colonel W. F. Harvey and Mr. Hamilton continue their research on cellular response to irritants and Lieut.-Colonel W. Glen Liston his work on hæmophilic bacteria in relation to influenza.

These and the many other inquiries summarised in the report are all of interest and, as is appropriate for a College of Physicians, they arise in the main from the materials of an active medical school and have a direct bearing on the ætiology and treatment of disease.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

B C G AT THE ACADEMY OF MEDICINE.

ON July 7th two communications were made to the Academy of Medicine on the subject of B C G. It may be remembered that the Academy nominated in February of this year a commission to inquire into certain matters concerning B C G. In a preliminary report this commission has presented the following conclusions with regard to one aspect of its researches. —the harmlessness of B C G: "There is no authentic case," it says, "in which B C G, given to an infant by the mouth or subcutaneously, has become changed and provoked virulent tuberculous lesions. In the great majority of cases B C G is well tolerated by the new-born infant, producing no disturbances, and in no way hampering the development of the infant. Only occasionally, transitory and slight incidents, the most frequent of which is polyadenitis, have been seen to follow the vaccination. These incidents are of the same kind as those observed as a sequel to all sorts of vaccination. The commission recalls the injunction that vaccination of the new-born infant in infectious surroundings should be supplemented by its removal from all tuberculous contagion for at least six weeks from *the date of birth.*"

The second communication on B C G was made by Dr. G. Kern, who has made a statistical study of the infant mortality in the district of Thann (Haut-Rhin) the *stationary* character of whose population, half industrial and half agricultural, has enabled him to avoid *at least one* pitfall of a health survey. During the years 1927–30 inclusive there were 5080 births in this district, and 1698, or 33·4 per cent., of the infants were vaccinated with B C G. In 1929, as great a proportion as 49·1 per cent. of the infants born in this year were thus vaccinated; in 1930 this proportion fell to 42·3 per cent. on account of polemical publications in the newspapers. During these four years the deaths from all causes during the first 12 months of life were relatively much more numerous among the non-vaccinated controls, for whom the mortality was 10·54 per cent., whereas it was only 4·76 per cent. for the vaccinated. In no case had the vaccination given rise to any pathological incident or interfered with the growth of the child. With the growing respect which the professional statistician infuses into the bosom of the ordinary mortal, Dr.

Kern has invoked the aid of Monsieur Moine, the expert statistician of the *Comité National de Défense contre la Tuberculose,* who has verified the above figures.

OVERCROWDING OF THE MEDICAL PROFESSION.

The commission recently appointed by the Academy of Medicine to study the overcrowding of the medical profession in France has begun most logically by asking itself whether the problem it has been set to solve actually exists. It has come to the conclusion, quite emphatically, that it does. It has also come to the conclusion that this overcrowding is really due in great part to the ease with which foreigners can obtain a medical degree in France. The commission is, accordingly, in favour of the Armbruster Bill, which has already passed the first reading in the Senate and which lays down certain restrictions to the entrance of foreigners into the ranks of the medical profession in France. These restrictions are such that the foreigner who wishes to practise medicine in France will have to pass the same tests and undertake the same obligations as a Frenchman—i.e., he will have to obtain the French "baccalauréat" and become a naturalised Frenchman and be subject to military service. It is, however, suggested that the privileges accorded to Rumania in this particular field should not be withdrawn. At present some six or seven Rumanians settle every year in France to practise medicine, and it has been suggested that Rumania should henceforth be rationed with the generous quota of some 12 to 15 medical degrees a year.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

THE RECOGNITION OF METHYL-ALCOHOL.

THE controversy as to the danger of inhaling fumes of methyl-alcohol may not be settled, but it may perhaps be admitted that in this land of prohibition the main danger of employing methanol as an antifreeze is that it will be drunk. The United States Public Health Service, anxious that no one shall have a legitimate excuse for this error, has come to an agreement with the manufacturers, by which methanol antifreeze will be coloured a uniform shade of methyl violet, and be made distasteful by chemical additions. Its container is to bear a warning label of specified design.

DROWNING ACCIDENTS.

Official and voluntary health organisations, including the American Red Cross, are now busy with the summer campaign for the prevention of drowning. When a death by drowning occurs during a "heat wave" it is usually used by the newspapers to swell the total of deaths attributed to heat. But, as a matter of fact, the seasonal loss from drowning is a heavy one, heat wave or none. In the last ten years the total deaths from drowning have risen by irregular stages from 5000 to 7000. About half of this mortality is recorded in June, July, and August. Examination of the statistics by age-groups reveals that the heaviest sufferers are youths from 15 to 19; the next heaviest, children from 10 to 14. More than half of these deaths occur before the age of 25.

CHLORAMINES IN WATER PURIFICATION.

The use of chlorine as a disinfectant in municipal water-supplies has given great satisfaction in a large number of American cities and is now almost standard practice. However, it has had one drawback: in the presence of even minute traces of phenolic waste chlorine gives rise to an exceedingly disagreeable taste. A new treatment has recently been introduced in which ammonia is first added to the water-supply and then chlorine, so that chloramines become the active disinfectant. The disinfection is not as rapid as with chlorine alone but chloramines have certain other advantages, besides the absence of "tastes" where phenol may be present. They are not rendered chemically inert by sunlight, as chlorine is, nor do they react as readily with organic matter. As a result the disinfecting action persists longer and is a greater protection in preserving water after it has been purified and while it is lying in the distributing system. Chloramine apparatus is now put on the market by the firms that manufacture chlorinators.

ALCOHOL AS CAUSE OF AUTOMOBILE ACCIDENTS.

In his latest report the Surgeon-General of th United States Army expresses alarm at the "continue increase in unnecessary deaths from automobiles." H points out that last year these were responsible fo 76 per cent. more deaths in the army than any oth one cause. All but 11 of the deaths occurred privately owned cars. In 54 cases the deceased we on pass, in 11 on duty, and in four on trips wi athletic teams, in three cases the status is n known. Mechanical defects in the car were responsib in only four cases. "In a very large percentage cases the accidents clearly occurred as the result faulty driving . . . and unfortunately too often th driver was partially intoxicated."

SUCCESS IN EARLY TREATMENT OF CANCER.

Results published by the New York State Insti for the Study of Malignant Diseases show that of a total of 1229 cases, 307, or about 25 per ce remained well five years or more after treatmen the majority, of course, the condition was adva at the time of treatment. Among the cases clas as early were 65 cancers of the lip, of which 47 w well after five years; 14 cancers of the uterus, of wh nine were well after five years; and 60 cancers of th breast, of which 34 were well after five years. Th best results have been obtained with the basal c epitheliomas.

A DIAGNOSTIC TEST FOR CANCER?

Two months ago[1] we commented on the highly technical work in which Dr. S. G. T. Bendien had given an account of specific changes in the blood serum, which he claimed to have discovered in disease, especially in cancer and tuberculosis. In connexion with this work the following statement has appeared in the lay press, as having been issued by the British Empire Cancer Campaign.

> On learning of the claim by Dr. Bendien, of Zeist, Holland, that he had discovered a method of diagnosing cancer by examination of the blood, the British Empire Cancer Campaign, following its regular procedure, instituted inquiries. As a result it was decided in agreement with Dr. Bendien to put the matter to a test. Samples of blood were taken from 38 persons, some cancerous (as determined by microscopic examination). These samples of blood were taken in London by a physician on the staff of a large London hospital and the test-tubes containing the samples were numbered. The numbers and corresponding diagnoses

---

[1] See THE LANCET, 1931, i., 1096.

were entered on a sheet of paper and placed in a sealed envelope. The samples of blood and the sealed envelope were then conveyed by Dr. Piney, scientific secretary of the investigation committee of the campaign, to Dr. Bendien's laboratory. Dr. Piney himself was unaware of the diagnoses and was present throughout the entire test.

Twenty-one specimens were tested—five were taken from ancerous patients, two from normal people, and fourteen rom patients with other diseases. Dr. Bendien correctly iagnosed the five specimens known to be from cancerous atients and the two taken from normal individuals. In ddition, he diagnosed one of the remainder as cancerous. urther investigation of this case in London has proved that is diagnosis was also correct in this case.

The above is a short statement of the facts, but the ritish Empire Cancer Campaign feels it necessary in the ublic interest to make the following comments:—

1. The discovery of Dr. Bendien appears to mark definite rance in cancer research in respect of the aid it brings diagnosis of cancer, but some time must elapse before e full value of the method can be obtained.

2. It is important to lay emphasis on the fact that this ood test is for diagnosis and for diagnosis alone.

It is obvious that this preliminary test is not equate to establish a method of diagnosis, and that much larger series of tests, not only on the serums of tients with cancer, but also of patients suffering m a variety of other diseases, will have to be made.

DRUGS, SURGICAL INSTRUMENTS, APPLIANCES, AND FOODS.

B.M.A. EXHIBITION AT EASTBOURNE.

HE usual trade exhibit was opened at Devonshire k on July 21st by the President-Elect, Dr. W. G. loughby. It was housed in a temporary building cially erected for the purpose and, despite the ression through which trade is passing, there was lly display of both new and well-tried products evices. Only a few items can be picked out for on from each stand.

Drugs and Pharmaceutical Preparations.

I. GENERAL DRUG EXHIBITS.

60 and 68] Allen and Hanburys (Bethnal Green, 2) drew attention, among their many preparations, Eucortone, a suprarenal cortex extract for use in ldison's disease; Byno Eugastrol, an extract of sh hog's stomach tissue for the treatment of, nicious anæmia; Byno Hepol, a palatable liver ract and malt preparation; I-so-gel, a sugar-free getable laxative, acting by absorption of fluid; d Euvalerol elixirs, containing valerian.—[30] mour and Co., Ltd. (Armour House, St. Martin's-Grand, E.C. 1), showed their well-known Glanoid and preparations, and also a concentrated fluid tract of liver; a new calves'-foot jelly; Chymol, nutritive, and invalid beef preparations.—[72] ayer Products, Ltd. (19, St. Dunstan's Hill, E.C.3), tracted the visitor's attention by a blue and silver and on which were displayed the latest results of eir research work; for example, Lacarnol, a ucleosid extract said to have a remarkable ffect on the coronary arteries in angina; Elityran, new thyroid preparation accurately standardised y its weight-reducing properties in guinea-pigs; nd Abrodil, an iodine medium for excretion pyegraphy; the well-known Avertin, Luminal, and ovalgin were also shown.—[62] Boots Pure Drug o., Ltd. (Nottingham), showed a range of drugs, ncluding Acriflavine, in sterile solution, powder, mulsion and solution tablets; Lederle's Antineumococcus serum; Hexyl-resorcinol, Insulin, iver extract, and a highly concentrated fluid extract f fresh liver, and Stabilarsan and Sulphostab.—51] British Colloids, Ltd. (Gorst-road, Park Royal, N.W.10), had their well-known Collosol preparations on view, among the newest being Tetanol, a Collosol calcium put up with vitamin D, for oral use—the calcium for injection being prepared without the vitamin, as vitamin is not absorbed by this route; preparations of iron with copper, notably collosol "F.C.V.D.," a combination of collosol ferrum and collosol cuprum with malt extract and irradiated ergosterol, copper having been shown fto activate other metals; and Colsul, 1 per cent. sulphur, now supplied in aqueous solution to avoid the pain caused by oil injections. Their collosol tannic sprayed adaptor has been designed especially for the rapid application of tannic acid to burns. [83] The British Drug Houses, Ltd. (Graham-street, City-road, N.1), showed a number of new products among theirmany well-known ones; Avoleum is a highly concentrated and standardised solution of vitamin A alone; Carotene is available in sugar-coated pellets, each containing 2 mg.; Livogen is a potent liver extract put up with hæmoglobin and vitamin B for secondary anæmias; Gaster Siccata B.D.H. is a stomach preparation resembling a dried milk; the B.D.H. ureamometer outfit furnishes a simple clinical apparatus for estimating blood-urea from a single drop.—[57] Burroughs Wellcome and Co., Ltd. (Snow Hill Buildings, E.C. 1), had, as usual, an attractive stand to display their tabloid, soloid, hypoloid and other products; an illuminated pyramid indicated the modern treatment of rickets, asthma, cardiac conditions and certain obstetric emergencies, and Kepler cod-liver oil with malt extract was recommended for rickets; Ephedrine, Diginutin, and Infundin are well known, but Tabloid carotene was here exhibited for the first time.—[11] Reed and Carnrick (distributing agents: Coates and Cooper, Ltd., 41, Great Tower-street, E.C. 3) displayed their gland preparations, drawing special attention to Nephritin, composed of cortex and convoluted cubules and used in acute nephritis; Ovacoids, containing entire ovary and anterior pituitary; Endomin, a kind of synthetic liver preparation containing all the known metallic compounds in liver ash; Thyracoids, a new biologically standardised iodothyroglobulin, and Brosedan, a bromide-yeast preparation.—[33] Evans, Sons, Lescher and Webb, Ltd. (56, Hanover-street, Liverpool, and 50, Bartholomew Close, E.C. 1), demonstrated the various specialities manufactured in their research laboratories, particularly an extract of suprarenal cortex; Hepatex, P.A.F., a solution of the liver fraction specific in pernicious anæmia, for injection; Hepovite, a compound elixir of hepatex; and Ephregel Nasal Jelly, a combination of ephedrine and adrenalin with analgesics and aromatics.—[44] C. J. Hewlett and Son, Ltd. (35–42, Charlotte-street, and 83–85, Curtain-road, E.C. 4), in addition to their old favourites Mist. Pepsinæ co. c. Bismutho and Liq. Ergotæ Purif., showed Hepatagen, an aperient and cholagogue; Veronigen, a barbitone hypnotic; and also useful general practitioner's and midwifery bags containing all essential equipment in an easily accessible arrangement.—[69] Hoffmann-la Roche Chemical Works, Ltd. (51, Bowes-road, N. 13), showed their well-known sedative preparations, of which Allonal and Sedormid were taken up Mount Kamet on the recent expedition, for the insomnia of heights; the handy Tubonic ampoule-syringes once more attracted interest.—[4] May and Baker, Ltd. (Battersea, S.W. 11), had many products on view, notably their preparations for venereal disease—"914" and others; Propidex, an ointment containing a mixed vaccine of streptococci, staphylococci, and *B. pyocyaneus*, for local vaccine therapy; Planocaine, a local anæsthetic less toxic than cocaine; magnesium hyposulphite in ampoules and tablets, for allergic conditions; Neptal, an organic mercurial diuretic; and Duracaine.—[76] Oppenheimer, Son, and Co., Ltd. (Handforth Laboratories, Clapham-road, S.W. 9), showed their familiar Palatinoids, Bipalatinoids, and Pulverettes, and also Dimol; Cocoids—tiny chocolate tablets for children—and Roboleine, the popular reconstructive food.—

Lieut.-Colonel FREMANTLE asked whether, as a result of this, the Secretary of State had advised people not to congregate on their holidays.

Mr. WESTWOOD said that the point of that supplementary question was not in the original question. He had answered everything in the question.

Replying to the Speaker, Lieut.-Colonel FREMANTLE pointed out that this was an extraordinarily serious question, on which all the country wanted advice. Action had already been taken on the advice of the Minister on those actual facts, and it was on those facts that he wanted to cross-examine the Minister.

The Speaker said that question time was not the time for cross-examination.

Mr. PYBUS asked if it was in order for a Member to ask a question which if it got into the press would damage the prospects of every seaside resort in the country.

Lieut.-Colonel FREMANTLE gave notice that he would raise the question, both in regard to the Ministry of Health for England and Wales and in regard to Scotland, on the Appropriation Bill.

Mr. MARJORIBANKS asked the Secretary of State for War whether, in view of the increase of meningitis in the army at home, he had taken any and, if so, what steps of a precautionary nature.—Mr. SHAW replied: I can assure the hon. Member that every possible precaution is being taken.

Mr. MARJORIBANKS asked if any steps had been taken in regard to the permanent buildings in which the army was situated, especially in regard to the winter months.

Mr. SHAW said that special precautions had been taken with regard to the sterilisation of utensils, with regard to ventilation, over-crowding and, above all, to the persons who were suspected of being carriers of the disease. He did not think there was need to make special provision with regard to the permanent buildings.

TUESDAY, JULY 28TH.

Road Accidents in London.

Mr. NAYLOR asked the Home Secretary how many fatal and non-fatal road accidents had occurred in the Metropolitan area since the abolition of the speed limit; and how many occurred during the corresponding calendar period prior to the abolition.—Mr. CLYNES replied: The figures are as follows:—Return of the number of accidents in which persons were killed or injured within the Metropolitan Police District during the months of January, February, March, April, May, and June, 1930 and 1931:—

Month.	1930.		1931.	
	Fatal accidents.	Non-fatal accidents.	Fatal accidents.	Non-fatal accidents.
January ..	118	3501	86	3016
February ..	102	2928	87	2804
March ..	98	3960	113	3259
April ..	112	4243	108	4011
May	109	4798	114	4727
June.. ..	109	*	116	*
Totals ..	648	19,430	624	17,817

* The figures for the non-fatal accidents for the months of June, 1930 and 1931, are omitted as those for the 1931 period are not yet available.

Opium Consumption in the Far East.

Mr. WELLOCK asked the Under-Secretary of State for the Colonies, whether any steps were being taken in British Colonies and Dependencies to carry out the recommendations of the Report of the commission of inquiry into the control of opium consumption in the Far East.—Dr. SHIELS replied: The recommendations have been carefully considered by the Governments concerned, but it is considered advisable to defer any changes in the existing system of control until the Commission's recommendations have been fully discussed at the International Conference which is to be held at Bangkok in November.

THE PLYMOUTH HOSPITALS.—The recent Plymouth Hospitals' Fair has produced £13,000. Last week the Mayor of Plymouth opened additions to Swilly Hospital.

ST. BARTHOLOMEW'S ADVISORY COMMITTEE.—The advisory revenue and expenditure committee, which it was recently decided to appoint, has now been constituted as follows: Sir Phené Neal (Lord Mayor of London), Lord Plender, Sir William McLintock, Mr. Cecil Lubbock, and Mr. Stanley Christopherson. The committee will advise on the financial policy of the hospital and on all proposals involving extraordinary capital expenditure or material increase in ordinary maintenance costs.

THE SERVICES

ROYAL ARMY MEDICAL CORPS.

Lt. (on prob.) W. A. Robinson, from the secd. list, is restd. to the estabt.

L. T. Furnivall to be Lt. (on prob.) and is secd. under the provisions of Art. 213, Royal Warrant for Pay and Promotion, 1931, from that date.

TERRITORIAL ARMY.

Lt. R. H. Yelf (late Loyal R.) to be Lt.

MEDICAL NEWS

University of Cambridge.

At recent examinations the following candidates successful:—

D.M.R.E.

Part II.—Walter Addey, William Ahern, G. S. Bhar H. W. Davies, G. C. Fairchild, C. P. Goswami, J. J. O'C and Thomas Simpson.

University of London.

On the occasion of the centenary meeting of the Brit Association in London next September the Senate decided to confer the honorary degree of Doctor of Sci on General Smuts, F.R.S., the President, and on Sir Gow Hopkins (the present President of the Royal Society), Rutherford of Nelson, O.M., Sir Charles Sherrington, O and Sir Joseph J. Thomson, O.M., all of whom have occu the same office.

At recent examinations the following candidates successful:—

FOURTH EXAMINATION FOR B.D.S.

Ronald Lawton, King's Coll. Hosp.; T. W. E. Pugh, Hosp.; and W. M. Sinclair, King's Coll. Hosp.

University of Edinburgh.

On July 22nd the following degrees and diplomas conferred:—

M.D.—† R. S. Begbie (in absentiâ), William Bird, ‡ Bloom (in absentiâ), E. M. R. Frazer, H. H. C. Fuller, ander Hood, F. M. Khan (in absentiâ), D. T. Mackie, Macqueen (in absentiâ), ‡ P. V. Pritchard, and J. O. Re absentiâ).

† Highly commended for Thesis. ‡ Commended for The

D.Sc.—Donald Mainland, M.B. (in absentiâ).

Ph.D.—J. C. David, M.B. (in absentiâ).

M.B., Ch.B.—N. S. Alcock, D. M. Anderson, * W. Arnott, J. B. Arthur, C. E. S. Bailey, G. M. Balfour, J Barnetson, J. C. Barnetson, I. M. Bell, C. H. Bentley, Berry, B. S. Bindra, W. G. Bisset, A. D. I. Weiss, Barbara C. Welsh, J. H. Wilson, R. B. Wilson, and Robert Woodrow.

D.T.M. & H.—A. A. F. Brown, and W. R. Duff.

Diploma in Radiology.—Angus Campbell, R. J. W. Charlton, A. J. Groenewald, D. G. Maitland, and W. S. Shearer.

The following awards were made: Syme Surgical Fellowship, John Bruce, M.B.; Gunning Victoria Jubilee Prize in Surgery, I. G. W. Hill, M.B.; Lauder Brunton Prize in Pharmacology and Therapeutics, C. M. Scott, M.B. Ettles Scholarship and Leslie Gold Medal, J. G. M. Hamilton, M.B.; Allan Fellowship n Clinical Medicine and Clinical Surgery, J. G. M. Hamilton, M.B.; Murchison Scholarship in Clinical Medicine, W. M. Arnott, M.B., and R. J. Kellar, M.B.; M'Cosh Graduate's and Medical Bursaries, H. A. Raeburn, M.B.; Mouat Scholarship n the Practice of Physic, P. C. M'Kinlay, M.B.; Buchanan cholarship in Midwifery and Gynæcology, R. J. Kellar, M.B.; ames Scott Scholarship in Midwifery, Arthur Lees-Low, M.B., nd J. A. Scott, M.B.; Beaney Prize in Anatomy and Surgery, hurth Carpenter, M.B.; Conan Doyle Prize, Israel Gordon, I.B.; Annandale Gold Medal in Clinical Surgery, R. J. Kellar, .B.; Murdoch Brown Silver Medal in Clinical Medicine, W. M. rnott, M.B.; Royal Victoria Hospital Tuberculosis Trust old Medal, J. H. Wilson, M.B.; Thomson Medal in Diseases Children, W. S. M'R. Craig, M.B.; Scottish Association Medical Education of Women Prize, Jean W. R. Paton, .B.; Dorothy Gilfillan Prize, Isobel O. Kennedy, M.B., and an W. R. Paton, M.B.; Wightman Prize in Clinical Medicine, J. Kellar, M.B.; Pattison Prize in Clinical Surgery, J. J. M. own, M.B.; Cunningham Medal and Prize in Anatomy, W. Armour, Ph.D.

The Cameron Prize in Practical Therapeutics has been awarded Madame Marie Curie, Director of the Curie Laboratories at the dium Institute of the University of Paris, "in recognition he fruitful therapeutic results which have been made possible her discovery of radium."

* With Honours.

yal College of Surgeons of Edinburgh.

At a recent meeting of the College, with Dr. James Haig rguson, the President, in the chair, the following 26 cessful candidates (out of 96 entered), who passed the uisite examinations between March 26th and April 4th, e admitted as Fellows:—

opinath Ganesh Ambegaokar, M.B. Bombay; David lliam Bawtree, M.B. Camb.; Andrew Johnstone Brown, .C.P., L.D.S. Edin.; James Roderick Johnston Cameron, .C.P., L.D.S. Edin.; Cecil Nathaniel Love Cantor, M.D. b.; Harold Carter, M.B. Edin.; Joseph Jefferson Coulthard, . Edin.; David Sydney Davies, M.D. Oxf.; James Bruce var, M.B. Edin.; Duncan Iain Campbell Finlayson, M.B. n.; Henry Parke Forster, M.B. Cape Town; Noel Gerald leton Gane, M.R.C.S. Eng.; Robert Grieve Hutchison, .F.P.S. Glasg.; John Godfrey Kingsbury, M.B. Lond.; n Eric Lane, M.R.C.S. Eng.; John Christian Mayo, Adelaide; John Horsfield Otty, M.B. Aberd.; Leslie thron Patrick, M.B. Edin.; Robert Gordon Paul, L.R.C.P. a.; Thomas Mackenzie Reid, M.B. Edin.; Edwin Moody ertson, M.B. Edin.; Eric Hugo Thomas Rutherford, M.B. and.; Robert Sampson, M.B. Edin.; Walter Netley Searle, N.Z.; Bronte Creagh Smeaton, M.B. Adelaide; and d Wardrop, M.R.C.S. Eng.

the same meeting Rebecca Evelyn Roulston, M.B. Glasg., passed the examination in 1930, was admitted a Fellow.

al Sanitary Institute.

ord Balfour of Burleigh has been elected President the Institute in succession to the late Duke of thumberland.

yal College of Physicians of Edinburgh.

quarterly meeting of the College was held on July 21st, h Sir Norman Walker, the President, in the chair.

Dr. George Hector Percival (Edinburgh), Dr. David Lees, inburgh), Miss Margaret Black Martin (Edinburgh), d Dr. Joseph Ryland Whitaker (Edinburgh) were introced and took their seats as Fellows of the College.—Dr. omas Douglas Inch (Gorebridge), Dr. Walter John May urban), Dr. Edward Robert Charles Walker (Aberdeen), d Dr. David Taylor Mackie (Exeter) were elected to e Fellowship.

Dr. James Collier (London) was appointed Morison cturer for 1932.

Research Fellowship.—In accordance with the bequest by rs. Isabella Kirk Duncanson, to commemorate the late r. J. J. Kirk Duncanson, the council will award a Kirk uncanson Research Fellowship next October. A Fellowship ill be awarded annually for a period of one year, and may e renewed for two additional periods of a year each. The molument will be upwards of £150 for the first year, about 250 for the second year, and about £350 for the third year. n making the first award special consideration will be given o the claims of candidates who propose to devote themselves o diseases of the ear, nose, or throat. Applications must e made in proper form before Oct. 15th.

nternational Surgical Congress.

The ninth congress of the Société Internationale de Chirurgie will be held in Madrid from March 15th to 18th, 1932, with Prof. F. de Quervain, of Berne, as president. The chief subjects of discussion will be tumours of the spine, non-tuberculous pulmonary suppuration, the surgery f the œsophagus, and surgical anæsthetics. For the first time since the late war the speakers will include representatives of German surgery. The address of the secretary-general, Dr. L. Mayer, is 72, rue de la Loi, Brussels.

National Hospital, Queen-square.

The out-patient department of this hospital will be closed during the first three weeks in August.

St. Mary's Hospital Dinner.

The annual dinner of past and present students of St. Mary's Hospital, London, will be held at the Trocadero Restaurant, Piccadilly-circus, on Friday, Oct. 2nd, at 7 P.M.

Argentine Medical Congress.

Lord Moynihan, President of the Royal College of Surgeons, has sailed for South America, where he is to represent the British medical profession at the coming congress at Buenos Aires.

St. Thomas's Hospital Dinner.

The old students' dinner will be held at the May Fair Hotel, Berkeley-street, London, W., at 7.30 for 8 P.M. on Friday, Oct. 2nd, with Mr. J. Herbert Fisher in the chair.

International Tropical Medicine.

An International Federation of Societies of Tropical Medicine and Hygiene has been constituted under the presidency of Prof. C. Achard, of Paris. The preliminary discussions took place at the invitation of the *Revue des Maladies des Pays Chauds*, and societies from some twenty countries have joined the federation.

German Pharmacological Society.

This year's congress of the Deutsche Pharmakologische Gesellschaft, which was to have been held at Vienna from Sept. 20th to 23rd, has been indefinitely postponed because of the economic situation in Germany and consequent difficulties of travel.

Medical Tour in Italy.

We are informed that there are still a few vacancies in the medical tour to Italian resorts and spas organised by the Italian State Tourist Department (E.N.I.T.) in September and October next. Members of the party will assemble at Rome on Sept. 18th and the tour will end at Palermo on Oct. 2nd. Particulars may be had from the British representative, Major W. Stormont, at 16, Waterloo-place, London, S.W.1.

Research Fellowships in Tuberculosis.

The Medical Research Council announce that they have awarded Dorothy Temple Cross Fellowships for 1931–32 to Charles Allan Birch, M.R.C.P., senior medical registrar and tutor at the Royal Infirmary, Liverpool, and to Roy Lars Vollum, D.Phil., demonstrator in pathology in the University of Oxford. Dr. Birch has received a Fellowship for the study of problems of tuberculosis at industrial centres in the United States. Dr. Vollum will study recent developments in methods for the investigation of tuberculosis, in Germany and Austria. The Fellowship awarded last year to Lieut. Sidney Malcolm Burrows, R.A.M.C., late clinical assistant in the Tuberculosis Department at St. Thomas's Hospital, has been renewed for a further year.

Epsom College, Founder's Day.

Founder's Day was celebrated at Epsom College on Saturday, July 25th, when the Chairman of the Council, Dr. Raymond Crawfurd, distributed the prizes and afterwards spoke to the boys on the true aims of education, —namely, the production of a healthy body, an active, intelligent mind, and steadfastness of character. He referred to the steps recently taken by the Council to extend the teaching of biology by making it a school certificate subject, and gave the boys a clear insight into the most pleasurable way of combining biology and natural history. The range of recreational activities had been extended, he added, by building four new hard tennis-courts, now nearing completion.

The headmaster, Mr. A. C. Powell, reported on the school's activities during the past year, and announced that Lord Dawson of Penn had agreed to open the new sanatorium on Saturday, Oct. 3rd. Among the beneficial results that would accrue from the building, not the least, he said, was that additional boys were able to be taken into the previous sanatorium as a waiting house, which now was necessary.

With the conclusion of the proceedings in Big School rain fell in torrents and an assault-at-arms, planned for the open air, had to be transferred, hurriedly, to the gymnasium, which could not possibly cope with everyone anxious to witness a most excellent performance. About 1000 guests were present at tea, and its says much for all concerned that the great majority braved the elements in order to witness in the evening an enjoyable production of "Patience" by the College Choral Society.

NOTES, COMMENTS, AND ABSTRACTS

THE HOSPITALS OF JAPAN.

(FROM A CORRESPONDENT IN TOKYO.)

JAPANESE hospitals may be said to have their origin in the Nara period (710–780). There were then established the *hiden-in* (medical treatment) and the *seyakuin* (medicine dispensing) institutions. They were organised and conducted by the Buddhists, and were nothing more than charitable institutions for social welfare. Later, in the Kamakura era (1185–1333) we find traces of the *ryobyoin* (charity hospitals) and the *hiden-in*, institutions of a similar nature, but without either accommodation or the elementary requirements of a modern hospital.

During the civil wars (1464–1586) Hideyoshi Toyotomi re-established the *seyakuin*, but it did not become a permanent institution. After this, Louis Almeida, the Portuguese, built a sort of combined leper hospital and orphanage, but this, again, was not maintained. It is noteworthy that from the introduction of medical science into Japan the foreigners have been the pioneers in caring for the lepers.

As early as 1722 Shogun Yoshimune Tokugawa built a kind of convalescent home within the grounds of what was then known as the Hakusan Medicine Garden, at Koishikawa, Tokyo. This is considered by the Japanese as the precursor of the first state medical institution. It was established on the advice of Dr. Sensen Ogawa, and at first accommodated 40 patients. This number had increased to 100 by the year 1723, and in 1729 the home was able to take 150 convalescents. Yoshimune Tokugawa also built a *seyakuin*, or "medicine-giving place." After this facilities were afforded for the treatment of patients in the so-called medical schools of the subordinate lords, or *dainyo*, as also in the private schools established by the eminent physicians of Edo (Tokyo), Osaka, and Kyoto.

Those places could not, of course, as yet be called hospitals in anything like the modern sense of the word, but a century later, in 1868, there came the Meiji restoration, when the medical school at the home of Todo, at Shitaya, Edo, was named the Dai Byoin (Great Hospital), and the original medical school was considered attached to it. In 1869 this Dai Byoin was annexed by the university. While this was taking place in the capital most of the medical schools of the leading clans, which had become absorbed in the empire, were transformed into medical schools and hospitals in the then modern sense. Some, however, were transformed into prefectural hospitals, so that to-day the prefectural hospitals of Kagoshima, Hiroshima, Gifu, Nara, Morioka, and Yamagata are the transformations of the old clan hospitals of the pre-Meiji feudal Japan.

Special hospitals dating from this time around the restoration are the Matsuzawa hospital for mental diseases, established in 1888, the Tokyo City Hospital (established in 1872), while in more recent times there are the Yokohama Juzen Hospital (1920) and the Kobe Shimin (Citizens') Hospital (1920).

Foreign Influence.

It would not be out of place to mention here that William Willis, an Englishman, introduced the English school of medicine to Japan in the first year of Meiji, 1868. He came to Japan for this purpose at the invitation of the Kagoshima clan. Willis rendered valuable service during the restoration, and as a mark of appreciation was appointed professor of medicine in the Tokyo Hospital attached to Igakusho, the nucleus of which is now the Imperial University of Tokyo.

At the present time the German influence is probably greatest—the pre-war prestige of German medicine being largely reinstated in Japan. American influence is almost exclusively limited to that of the variou missionary societies. At St. Luke's Hospital, th largest and most important of the American or foreig institutions, it is proposed to establish a medic faculty by amalgamation with the American privat university of Rikkyo (St. Paul's College).

Private and Public Benefactions.

Among the hospitals built by Japanese philan thropists the most important to-day are the Mits Philanthropic Hospital (1909), the Yamaguchi Kos Hospital (1925), and the Okayama Tuberculos Hospital. The Red Cross Society, which was establishe in 1882, and increased considerably in importan with the Sino-Japanese war, in 1894, and the Russ Japanese war, in 1904, has its chief hospitals in Toky with branch hospitals elsewhere. Osaka has also i Electric (Bureau) Hospital, while the railway offi has its own hospitals in six of Japan's largest towns- Tokyo, Nagoya, Osaka, Sendai, Moji, and Sappo Other hospitals of importance are those establish by the charity organisations, of which the best know is that belonging to the saiseikai, or relief associatio This was founded by the money and encourageme of the Emperor Meiji himself, who intended it as philanthropic hospital for the poor. With its imper patronage the saiseikai built its head hospital Tokyo, with branch hospitals in Osaka, Kanaga Hyogo, Fukuoka, Kyoto, and Kochi. It also cont 41 clinics, 3 tuberculosis hospitals, 1 orphanage, 15 itinerary medical corps, and it receives an an state subsidy of £25,000.

Present Position.

The present state of Japanese hospitals gives g promise for the future, but, unfortunately, there an increasing number of private clinics which make establishment of larger and better-equipped ins tions more difficult.

Leprosy, Tubercle, and Mental Disease.

The Government has at last taken steps to augm the Empress Dowager's grant for the establishmen leper hospitals, which was, perhaps, Japan's m pressing need. Though the Government's plan eradicate leprosy within 30 years is not thou feasible by the medical and other critics, it is m encouraging to see that at last an attempt is be made to promote the work begun and carried on years, almost unaided, by foreign Christian missio The same may be said of the tuberculosis sanatoriu Here, too, the Government has decided on th establishment of sanatoriums throughout the countr but in view of the large number of tuberculous peop within the Empire the scheme even when complete wi be quite inadequate.

Another branch of medicine sorely neglected i Japan at present is the treatment of mental diseas Here the State has done little so far, and for the moment there appears little prospect of anything bei done officially. In a country where it is considered the family's painful duty to care for its own idiot children, and where, at the same time, it is believed to be a curse of the gods if a family should number an idiot among its members, it may well be imagined what is the general fate of lunatics. Fortunately there is nowadays a healthy reaction in these and other matters—thanks largely to the Japanese and foreign English press.

The raising of women's status in Japan will no doubt serve to abolish many abuses, and must also considerably advance the welfare of children. The first Women's Suffrage Bill, which was recently introduced in the Diet, was rejected by the House of Peers after having passed the Lower House, but a long-closed door has begun to open. That Japan is daily taking an increasing interest in medicine and eugenics is patent to all who are in any way acquainted with the country.

NICOT AND THE DISCOVERY OF TOBACCO.

THE fourth centenary of the birth of Jean Nicot, French ambassador to the Court of Portugal from 1559 to 1561, was the occasion last year of much celebration of his fame as the discoverer of tobacco. Dr. Paul Koenig[1] holds this reputation to be undeserved. Although, he says, Nicot did much to popularise this herb in France, it had been known In Europe before his birth. Dr. Pedro Martyr de Angleria, a friend of Columbus, published in Seville, n 1511, and in Paris 21 years later, a work entitled De Rebus Ocenanicis et de Orbo Novo Decades Tres, n which he mentioned the account of tobacco ommunicated to Columbus in a letter by Fray Romano Pane, who had remained in Hispaniola as a missionary. The honour of first bringing tobacco to France belongs, according to Dr. Koenig, to a armelite called André Thevet, who went to Rio de aneiro with the Maltese knight Nicolas Durant n 1555. In 1558, Thevet described the plant in a book (which probably contains the earliest extant escription of a cigar) and cultivated it under the ame of "l'herbe angoulmoisine," after his birthplace, Angoulême. Nevertheless, Thevet did nothing popularise tobacco, and in the opinion of Dr. Koenig was probably growing *Nicotiana rustica*, hich his friends would have found too strong. ccording to the more credible of two accounts, icot saw the plant flowering in the garden of the lace at Seville, begged some seeds from the d gardener, and raised them at the Embassy. learned its therapeutic properties—perhaps, Koenig suggests, from Prof. Nicolo Monardes, o then occupied the chair of medicine at Seville—d called it the "Wonder-plant." He succeeded curing ulcers and wounds with applications of the h leaves, and soon acquired great fame, first in bon and then in Paris. He named tobacco icotiana" after himself, and, as a step towards perpetuation of this name, incorporated it in the tionary of the French language which he compiled. was displaced in popular speech by various forms the word "tabaco," the aboriginals' name for their e, but has survived in the language of botany, the fame of Nicot has been immortalised in the me of the alkaloid nicotine, first isolated at idelberg in 1828 by Reinmann and Posselt. Nevereless, to judge by the present importance of bacco in civilised life, it is doubtful whether any man was ever indispensable to its popularisation Europe. It entered England independently of icot, and if he had not brought it to France from ortugal someone else would certainly have brought in from this country.

A NEW ARC LAMP.

WITH the ordinary open carbon arc running on irect current, the potential difference across the lectrodes is about 45 volts. The difference between his value and the voltage of the supply has to be aken up in a series resistance. This involves much oss of efficiency, since only a small proportion of he power drawn from the main is employed in the rc itself. Any attempt to increase the potential ifference across the electrodes by increasing the ength of the arc results in irregular running conditions. The length of an enclosed arc can be considerably increased without producing this effect, but for therapeutic work the glass container absorbs the effective part of the radiation.

The Kandem arc, recently put forward by Messrs. Korling and Mathiesen, of Leipzig, is a successful attempt to get over these difficulties. The arc is struck between two cored carbons mounted horizontally in a cylindrical metal housing. *In the front* of this chamber a rectangular window is cut. The window is not glazed or covered in any way. The arc is controlled by an automatic mechanism to run at a length of about 2½ in., but owing to the enclosure the discharge is perfectly steady. A magnetic blower is fitted in such a position as to flatten the arc so that it is a horizontal flame, and not bent into an arch as otherwise it would be by the upward current of hot gases. Owing to the length of the flame the potential difference across the electrodes is 110 to 120 volts. Hence a much higher proportion of the energy drawn from the mains is applied to the generation of ultra-violet radiation instead of being lost as heat in the series resistance. It has been shown by Angus that in the carbon arc a long flame is more efficient for the same current than a short one for therapeutic application, because the valuable radiation comes from the discharge rather than the incandescent electrodes.

Other advantages, too, are claimed for mounting the arc in a partially enclosed chamber. It has been found that any carbon monoxide produced will be oxidised completely to carbon dioxide in the heated enclosure. Further, the oxides of the metals used in coring are deposited on the inside of the cylinder and do not escape into the room as with the ordinary type of arc. The presence of any dangerous concentration of CO in a room in which a carbon arc is run has not so far been reported, and probably ventilation would have to be very inefficient for such conditions to develop; but the fumes of oxide from metallic and cored metallic arcs have been found unpleasant when prolonged treatment is employed as in a hospital or clinic.

To summarise: the Kandem arc is a new development employing carbon or cored carbon arcs. The arc is of high efficiency, giving a large output of ultra-violet radiation for the power consumed. The steadiness of running results in a very uniform intensity, a point of much importance in therapeutic work. The lamps are made to work on D.C. and A.C. supply, and in two sizes for 6 and 24 amps. respectively.

GUIDE TO CURRENT OFFICIAL STATISTICS.

THE ninth volume of this guide, which covers the whole of the statistical information contained in official publications in 1930 by government departments in Great Britain and Northern Ireland, has just been issued and may be obtained from H.M. Stationery Office (1s.). It is issued by the Permanent Consultative Committee on Official Statistics, London, and its object is to direct the inquirer to all official publications that contain statistics bearing on the particular subject with which he is concerned, and more especially to inform him of the nature of the statistics he will find in the volumes to which he is referred—i.e., the mode of analysis and the time and place to which they relate. There are two distinct sections in the book: (1) An alphabetical subject index with indicating numbers, and (2) a list of publications in numerical order.

"HIDDEN POWER."

Dr. Charles Russ's play, called "Hidden Power," is being presented again in London by the Warwick James repertory company. It is a drama full of medical interest, for its opening (and only) murder is committed by the anæsthetist during an operation, and his guilt is subsequently discovered by hypnosis. This gives Dr. Russ a good opportunity for discussing, through his characters, some important aspects of mind and body, and he makes suggestive comments on psychological analysis as practised by doctors and clergy. At the same time he contrives a number of startling situations, and at moments of crisis in the consulting room it is soothing to refer to the programme and find the names of well-known surgical instrument makers in place of the usual "wigs by Clarkson." It must be admitted, however, that the play lacks surprises, and it certainly requires ruthless compression. It only begins to live in the *third* act, and the fifth betrays its origin in an afterthought. Perhaps we could not reasonably expect the heroine's little son to have grown in stature since we first met him two years before; but he still seemed deplorably young for his original age.

---

[1] Münch. med. Woch., July 3rd, p. 1144.

The play is to be seen at King George's Theatre, Caroline Street, Great Russell Street, London, W.C.1, until the end of this week.

DIETETICS.

A WORK [1] whose author endeavours to omit all medical details and yet to deal with a most important branch of therapeutics must suffer from certain limitations. This one is easily understandable by the layman, but as the layman is not likely to be so unlucky as to suffer simultaneously from acute colitis, constipation, diabetes, dysentery, gastric ulcer, gout, hypertension, and obesity, it must necessarily tend to tempt him to take an undue interest in subjects which are not his concern. If, on the other hand, it is intended for the medical man, he is bound to be somewhat disappointed to find the dietary for gastric ulcer, for example, confined to Leuber's diet or Panzalt's diet, neither of which is frequently advocated in this country. The diets laid down with the dogmatism of capital letters in such conditions as hypertension, gastritis, and rheumatism lack scientific support. For these reasons we are unable to commend the book.

THE MEDICAL DIRECTORY.

Messrs. J. & A. Churchill write: "The annual circular has been posted to each member of the medical profession. If the form has not been received, a duplicate will be sent on request. We shall be grateful for the return of the forms by an early post."

SULPHUR TREATMENT of G.P.I.—Commenting on the opening sentence of an annotation on this subject in THE LANCET last week (p. 200), Mr. J. E. R. McDonagh points out that he was using organic compounds of sulphur in the treatment of G.P.I. in 1916 [2]—that is nine years before sulphur was suggested as a pyrexial agent in substitute for malaria.

Appointments

FLETCHER, E., M.B. Camb., M.R.C.P. Lond., has been appointed Assistant Physican to the Queen Mary's Hospital for the East End.

SAVIN, L. H., M.D. Lond., M.R.C.P. Lond., F.R.C.S., Junior Ophthalmic Surgeon to King's College Hospital.

STOTT, W., M.B., B.S. Durh., D.P.H., Medical Officer, Southwark.

Certifying Surgeons under the Factory and Workshops Act: HARRISON, C. B., L.R.C.P., L.R.C.S. Irel. (Youlgreave, Derby); HENDERSON, W. (Burgess Hill, Sussex); SCOTT, W. J., M.B., Ch.B. Glasg. (Annbank, Ayr); TAYLOR-JONES, T. H. E. (Tenderden, Kent).

Vacancies

For further information refer to the advertisement columns.

Accrington, Victoria Hospital.—H.S. £150.

Altrincham General Hospital.—Sen. and Jun. H.S. At rate of £150 and £100 respectively.

Ashton-under-Lyne, District Infirmary.—H.S. At rate of £150.

Bangor, Carnarvonshire and Anglesey Infirmary.—H.S. £200.

Barnsley, Beckett Hospital and Dispensary.—H.P. £200.

Barnstaple, North Devon Infirmary.—Res. M.O. £150.

Bath, Royal United Hospital.—Sen. H.S. At rate of £175.

Bedford County Hospital.—Asst. H.S. At rate of £130.

Benenden, Kent, National Sanatorium.—Res. Asst. M.O. £300.

Birkenhead Infirmary and Institution, Tranmere.—Res. Asst. Med. Supt. £450.

Birmingham, Midland Hospital, Easy-row.—H.S. £150.

Bolingbroke Hospital, Wandsworth Common, S.W.—Res. M.O. £200.

Bootle General Hospital, Nr. Liverpool.—H.P. At rate of £150.

Bradford, City.—Asst. School Dental Surg. £475.

Bradford, Municipal General Hospital, St. Luke's.—H.P.'s and H.S.'s. Each at rate of £200.

Brighton, Royal Sussex County Hospital.—Cas. H.S. £120.

Brighton, Sussex Eye Hospital.—Hon. Clin. Asst.

Bristol General Hospital.—H.P. At rate of £80.

Bristol, Stoke Park Colony.—M.O. £600.

Cambridge, Addenbrooke's Hospital.—Res. Anæsthetist and Emergency O. Also H.P. Each at rate of £130.

Cancer Hospital, Fulham-road, S.W.—Physiological Chemist. £600.

Chesterfield and North Derbyshire Royal Hospital.—H.S. At rate of £150.

City of London Hospital for Diseases of Heart, and Lungs, Victori Park, E.—Registrar.

Coventry and Warwickshire Hospital.—Res. H.P. and Res. Cas. O. £160 and £125 respectively.

Dewsbury County Borough.—Deputy School M.O., &c. £600.

Doncaster, Royal Infirmary.—H.P. At rate of £175.

Downpatrick, Northern Ireland, Down Mental Hospital.—Asst. M.O. £300.

Dudley, Guest Hospital.—H.S. Also Asst. H.S. £200 and £1 respectively.

East Ham, County Borough of.—Asst. M.O. £500.

Elizabeth Garrett Anderson Hospital, Euston-road.—Clin. Asst

Evelina Hospital for Children, Southwark, S.E.—H.S. At rate £120.

Great Yarmouth General Hospital.—H.S. £140.

Hove, Lady Chichester Hospital.—Jun. H.P. At rate of £5

Huddersfield Royal Infirmary.—H.S. At rate of £150.

Hull Royal Infirmary.—H.P. to Sutton Branch. £160.

Ipswich, East Suffolk and Ipswich Hospital.—4 H.S.'s an 1 H.P. Each £120.

Leeds Hospital for Women.—H.S. At rate of £100.

Liverpool, Royal Children's Hospital.—Res. M.O. Also Secon Res M.O. At rate of £180 and £120 respectively.

Leicester Royal Infirmary.—H.S.'s and H.P. Each £125.

Liverpool Heart Hospital.—Hon. Asst. Phys.

London University, S.W.—University Readership in Patholo £800.

Lurgan Union, Northern Ireland.—M.O. £300.

Manchester, Ancoats Hospital.—Res. M.O., £150. H.P., and Orthopædic H.S. All at rate of £100. Also Pathologist (Part-time) £200.

Manchester, Hulme Dispensary.—Res. M.O. £300.

Manchester, Northern Hospital for Women and Children. Sen. H.S. and Jun. H.S. £130 and £100 respectively.

Manchester Royal Infirmary.—Asst. Res. M.O. and Res. Pathologist. £100.

Manchester Royal Eye Hospital.—Jun. H.S. £120.

Manchester and Salford Hospital for Skin Diseases.—H.S. rate of £100.

Margate Royal Sea Bathing Hospital for Surgical Tuberculo H.S. At rate of £200.

Marseilles, Queen Alexandra Memorial Hospital.—Res. £250.

Mount Vernon Hospital, Northwood.—H.S. At rate of £1

Nottingham General Hospital.—Cas. O. At rate of £2

Nottingham and Midland Eye Infirmary.—Res. H.S. £2

Plymouth Mental Hospital, Blackadon.—Deputy Med. £500.

Preston, Sharoe Green, Hospital, Fulwood.—Jun. Res. M.O.

Preston and County of Lancaster, Royal Infirmary.—Surg. £300.

Princess Louise Kensington Hospital for Children, Kensington, W.—Clin. Asst.

Queen Mary's Hospital for the East End, E.—Hon. Ophth.

Rainhill, Lancs County Mental Hospital.—Locum Te 7 gns. weekly.

Reading, Royal Berkshire Hospital.—Res. Anæsthetist. At of £150.

Rotherham Hospital.—Sen. H.S. £200. Cas. H.S. £150. H.P. £180.

St. Giles Hospital, Brunswick-square, S.E.—Asst. M.O.

St. Leonards-on-Sea, Buchanan Hospital.—Jun. H.S. £1

Salford, Hope Hospital.—Res. M.O. £400.

Sheffield Royal Hospital.—Ophth. H.S. Also Anæsthe £120 and £80 respectively.

Sheffield Royal Infirmary.—Asst. Aural and Ophth. H.S. H.S. and Second Asst. Cas. O. Each at rate of £80.

Southampton, Borough Isolation Hospital.—Res. M.O. £

Swansea General and Eye Hospital.—H.P. £150.

Walsall General Hospital.—H.P. and H.S. (Women). Each rate of £150.

Walsall Manor Hospital.—Asst. M.O. £150.

West Bromwich and District General Hospital.—H.S., H.P. an Cas. H.S. Each at rate of £200.

Westminster Hospital, Broad Sanctuary, S.W.—Wander Scho and Reg. to Children's Dept. £250.

Woolwich and District War Memorial Hospital, Shooters H S.E.—H.S. At rate of £100.

Wolverhampton and Midland Counties Eye Infirmary.—H.S. £1

Wolverhampton Royal Hospital.—H.S. for Women's Hosp. £1

The Chief Inspector of Factories announces vacancies f Certifying Factory Surgeons at Littleport (Cambridg and at Worthing (Sussex).

Births, Marriages, and Deaths

BIRTHS.

BATEMAN.—On July 23rd, at "Redlynch," Cooden, Bexhil the wife of Dr. C. E. Gooderson Bateman, of a son.

MOLESWORTH.—On July 20th, the wife of H. W. L. Molesworth, F.R.C.S., of a daughter.

TROUP.—On July 23rd, at The Farm House, Stonebridge, N.W.10, to Jean, the wife of Arthur G. Troup, M.D., D.P.H. —a son.

DEATHS.

HILLIER.—On July 25th, after a short illness, Thomas Ernest Hillier, M.A., M.B. Camb., aged 71 years.

SMITH.—At a nursing home in Sheffield, Charles William Smith, M.B., F.R.C.S., aged 53.

WATSON.—On July 27th, at Rainhill, Liverpool, George Alfred Watson, M.B., C.M. Edin., late Pathologist, Lancs Mental Hospitals Board.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages and Deaths.

ADDRESSES AND ORIGINAL ARTICLES

ON VACCINE THERAPY AND IMMUNISATION IN VITRO.

BY SIR ALMROTH WRIGHT, K.B.E., C.B., M.D., D.SC. DUB., F.R.S.,

PRINCIPAL OF THE INSTITUTE OF PATHOLOGY AND RESEARCH, ST. MARY'S HOSPITAL; PROFESSOR OF EXPERIMENTAL PATHOLOGY IN THE UNIVERSITY OF LONDON.

(*Continued from p. 230.*)

Antibacterial Power of Blood.

I ACCORDINGLY set myself to devise methods for measuring, first, the hæmobactericidal power exerted y the blood and its population of leucocytes upon erophytic organisms such as the staphylococcus, treptococcus, pneumococcus, and the tubercle bacillus. he problem I set myself here was to find, not a ethod of explantation to tell us what number of erophytic microbes are killed off without residue, ut a method of inculturing to tell us what percentage enumerated microbes implanted would grow out to colonies in the blood. The reason why the one nd not the other kind of method is required to easure the effect exerted by the blood by serophytes ll presently be apparent.

The slide cell method which makes use of defibri-ted blood was one of the methods of inculturing vised for this purpose. It is illustrated in Figs. 1 d 4, and is one of the methods put to use by Fleming his experiments on the action of antiseptics.

A second method devised for the same purpose the following:

Graduated implantations of microbes are made into coagulated instead of into defibrinated blood, and the planted blood volumes are then drawn up into capillary bes. After overnight incubation the capillary clots are own out, are treated with 1 per cent. saponin, and are then ng up in water until their colour is completely discharged. hey are then dried and stained, and the colonies are umerated under the microscope.

his, of course, gives—in particular in the case when e colonies are close-packed—a more accurate numeration than the naked-eye observation which e trust to in the slide-cell method. It also gives us ndications as to the rôle which phagocytosis plays n the killing of microbes. For the colonies found n the clots can be ranged into three classes: *naked olonies*—i.e., those which are not surrounded by eucocytes; *ringed colonies*, colonies surrounded with eucocytes; and what we may call blind, blank, or *obliterated colonies*—i.e., aggregations of leucocytes surrounding a presumably extirpated bacterial colony.

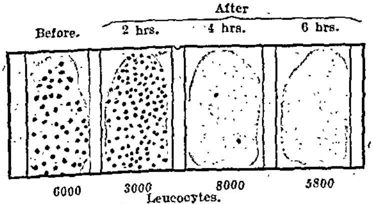
A third method—and this differs from the second only in the mode of implantation—is the "wash and afterwash" method. Here we draw up into a long capillary tube, first as a forerunner, a diluted bacterial culture, and then follow on with 10 equal volumes of blood separated off in each case by a bubble of air.

I will now relate what these methods have taught us about immunisation and the killing of serophytic microbes by the blood. Let me first explain the following points:

To begin with, the normal serum constitutes a very excellent culture medium for the class of microbes we are here considering. The same holds of the plasma. This, since the plasma is always full of blood-platelets, means incidentally that these formed elements also can here be dismissed from consideration. Further, the red corpuscles can, in appraising the bactericidal powers of the blood, be neglected. That follows by the fact that deleucocyted blood—i.e., the mixture of red corpuscles and serum which is obtained by passing blood through a close filter[12]—is as good a culture medium for serophytes as clear serum. It follows from this galaxy of premises that the bactericidal action which is exerted by a blood upon serophytic microbes is neither more nor less than the bactericidal action exerted by its population of leucocytes.

The next issue which comes up in connexion with the killing of serophytes by leucocytes is that as to whether these microbes are killed exclusively by phagocytosis followed by intracellular digestion; or whether they are killed also, and if so to what extent, extracellularly by bactericidal elements elaborated by the leucocytes and excreted by them into the serum.

FIG. 4.



Coli vaccine, 200 millions (intravenously). Tested in a slide cell by implanting 225 streptococci into 50 c.mm. of blood.

Important data which have, as we shall see later, a bearing upon this question, are furnished by a study of the event of adding graduated quanta of serophytic microbes to equal volumes of blood.

FUNDAMENTAL EXPERIMENTS.

I have already published experiments bearing on this question. But it will be convenient to give a concrete illustration of what happens when my blood (it is a blood of somewhat low staphylobactericidal power) is implanted with different quanta of staphylococcus. I subjoin protocols of two typical experiments confining myself for the moment to experiments carried out in slide cells.

Expt. 27.7.22.—Forty c.mm. volumes of A. E. W.'s defibrinated blood implanted with different quanta of staphylococcus culture and cultured in slide cells. (Table I.)

Expt. 1.8.22.—Graduated dilutions of staphylococcus culture were implanted into measured volumes of A. E. W.'s blood. The blood was then tested by two observers. (Table II.)

The explanation of the fact that the implanted microbes are here in no instance killed off without residue is furnished by the consideration that extracellular killing involves close proximity, and phagocytosis actual contact, between the microbes and leucocytes. In connexion with these requisites attention must be given to the following series of facts: (1) there are always in the blood large areas unoccupied by leucocytes (the volume of the contained leucocytes stands to the volume of the containing blood in the ratio of about 1 to 300); (2) these regions are for the major part leucocytically unpatrolled or very ineffectively patrolled; and (3) since it can, by appropriate experiments, be shown that leucocytes are insensitive to the feeble chemotatic stimuli which emanate from single microbes, the finding of isolated leucocytes by microbes must—even in patrolled areas in the blood—be a matter of chance. In other words, it depends upon the microbe happening to lie directly in the path taken by the leucocyte.

The fact that with larger and larger implantations larger and larger numbers of microbes are killed, shows that the blood develops under the impulsion of microbic stimulation increased bactericidal power.

INTERPRETATION OF THE DATA.

From this then follows the important principle that our methods of hæmobactericidal measurement are not in the same category as quantitative chemical tests. They are, in reality, biological tests; tests which tell us not what amount of bactericidal energy is actually resident in a sample of blood, but what bactericidal energy can, under the impulsion of microbic stimulation, be developed in that blood. In other words, they are comparable to tests made to find out what amount of muscular power can, under stimulation, be put forth by a muscle.

It is pertinent to note in passing that the general principle of which we have illustration here may hold true, not only of bactericidal, but also of opsonic power. It is conceivable that the values for opsonic power which are registered when microbes are incubated with a mixture of serum and leucocytes may represent, not as hitherto assumed, the native opsonic power of the serum, but native opsonic power supplemented by opsonins excreted into the serum by leucocytes under the impulsion of a microbic stimulus. Experimental data which bear upon this question will come up for consideration later. For the moment it will suffice to point out that by centrifugalising instead of incubating a phagocytic mixture, and by conducting our phagocytic operations at the temperature of the air instead of at blood heat, we can reduce the exposure of the leucocytes to microbic stimulation to a minimum.[13]

The Immunising Response.

Now that our measurements of the bactericidal power of the blood have brought us face to face with the conception of immunising response to the inoculation of microbes into the blood in vitro it will be appropriate to explain the genesis of that idea.

My first experiments on the question of immunising response made by the blood were prompted by th fact already mentioned that we had, despite strenuo experimental search, failed to find any indicatio of the production of antibacterial substances by the fixed tissues. In view of that I performed the following experiment:—

> Having placed double ligatures loosely round the jugu vein of a rabbit and having tied off all tributaries, vacc was introduced into the vein of the opposite ear, and the upon the double ligatures were drawn tight so as to iso a portion of the vaccinated blood within the jugular ve At the same time a sample of the vaccinated blood withdrawn from the carotid and was placed in the incub

Experiments of this kind showed that the antibacte response was obtained, not only in the circulati blood, but also in the blood isolated in the vein; and in addition in the blood which was isolated and incubated in vitro.

These experiments were followed by others in whic graduated doses of a staphylococcus and also of streptococcus vaccine were added to my own bloo in vitro. The inoculated samples of blood were the incubated for six hours and afterwards the ser were pipetted off, and then using the "wash and afterwash" procedure 10 volumes of each serum were implanted with a mixture of staphylococci and streptococci. The separate volumes of serum in question were then, after overnight incubation, explanted upon agar. These experiments showed (*a*) that the serum of blood implanted with an appropriate dose of a staphylococcus or streptococcus vaccine becomes bactericidal to both species of microbe; and, further (*b*) that the sera of the bloods implanted with an overdose of vaccine furnish, as compared with the serum of the uninoculated blood, a more favourable culture medium for both kinds of microbe.

The next important step undertaken—but this had to wait until the slide cell and other hæmobactericidal methods had been devised—was to investigate, as we have just done, the effect of adding graduated quanta of serophytic microbes to the blood.

IMMUNISING RESPONSE IN VITRO.

I have now, for 12 and more years, experimented continuously upon the immunising response of blood in vitro.

In addition to examining for augmented and educed bactericidal power in the blood taken as a hole, I have analysed the results which relate to this y chiastic bactericidal experiments. Further, I ave searched for augmented and reduced bactericidal ower in the serum—I use here the term reduced s well as the term augmented for the reason that he normal serum, though it is as good a culture nedium for staphylococci as nutrient broth, urnishes, there is reason to think, less than 100 olonies for 100 implanted staphylococci. I have urther looked for increased and decreased phagocytic esponse; for increased and diminished opsonic ower; and for negative and positive changes in the hagocytic avidity of the leucocytes—keeping n view all the time the problem of the rôle played y each of these items in the general bactericidal ower of the blood.

---

[13] *Fleming*: On Wright's Centrifuge Method of Estimating Phagocytosis, Brit. Exp. Path., 1927, viii., 50.

I have employed also as antigens, both living and lead, and in some cases, autolysed microbes, testing he resulting immunising response upon both homoogous and heterologous cultures.

Moreover, I have experimented upon the blood before clotting, upon coagulated blood, upon defibrinated blood, and upon isolated leucocytes—either eucocytes which had emigrated from the blood, or eucocytes separated by centrifugalisation.

Again, I have brought living or dead vaccines nto operation sometimes by incorporating them into he blood; and at other times by placing a blood ontaining vaccine upon or side by side with a blood ontaining a test-quantum of microbes (*Method of Felded Clots*); and, finally, I have—and this is also n effective method of vaccination—inoculated the eucocytes intracellularly. The procedure here in uestion (I call it the '*baiting method*') consists in aking two samples of blood, giving the leucocytes n one sample, a somewhat sparse phagocytic meal f microbes; and then supplying, after an interval f incubation, both the fed and the unfed populations f leucocytes with a full phagocytic test-meal.

In view of the wide domain covered by these experiments, I must confine myself to setting out here only the most important experimental findings.

Let me begin with the results of the chiastic experiments.

Expt. I., 29.8.23.—Simple bactericidal experiment in slide cells and also chiastic experiment. (Observer—L. C.). (Tables III. and IV.).

TABLE III.—*Hæmobactericidal Experiment.*

Blood B.—Index of hæmobactericidal efficiency 3·3; index of the bactericidal efficiency of the serum, 1·45; index of bactericidal efficiency of the leucocytes, 2·8.

Female student inoculated with 1000 million staphylococci subcutaneously. Blood A taken before the inoculation; Blood B four hours after. Both bloods were tested with three different suspensions of staphylococcus—2·5 c.mm. of each being added in each case to 50 c.mm. of blood.

Expt. II.—Inoculation in vitro.—A 100 c.cm. volume of R. T. M.'s unvaccinated defibrinated blood, and also a 100 c.mm. volume of his blood vaccinated with 1,000,000 of dead staphylococci per c.cm. The bloods were then incubated for one hour. After that the sera were pipetted off and the corpuscles washed in saline. Then in each case one volume of washed corpuscles was mixed with one volume of serum, and then 50 c.mm. volumes of each mixture were implanted with one-twentieth volume of graduated dilutions of staphylococcus culture. The implanted bloods were then cultivated in slide cells. (Table V.).

Vaccinated Blood.—Index of hæmobactericidal efficiency, 0·64; index of the bactericidal efficiency of the serum, 2; index of the bactericidal efficiency of the leucocytes, 0·5.

The results, you will see, of these experiments are inconclusive as to the relative importance of the part played by the leucocytes and the serum in the general bactericidal effect.

I must therefore pass on to other experiments. And let me, in order that these may be followed properly, point out that the number of serophytic microbes killed by the blood is determined largely by the disposition of the population of leucocytes relative to the population of microbes, and this disposition is, of course, modified by every physical force that comes into operation upon the blood.

The forces which here require to be considered are: (*a*) the force of gravity; (*b*) the compressional force exerted by the contraction of the clot; (*c*) the effect of centrifugalisation respectively upon uncoagulated, defibrinated, and coagulated blood; and (*d*) the spontaneous movements of the leucocytes.

With regard to the effect of gravity this comes into consideration in particular when we are operating with defibrinated blood. For here the red corpuscles and leucocytes settle to the bottom; and the microbes are left floating in the supernatant serum. They are there safe from phagocytic attack, and can, if the serum continues to be non-bactericidal there develop into colonies.

The spontaneous contraction of the clot influences the results by bringing closer together the leucocytes and microbes which were in the unclotted and freshly clotted blood comparatively far apart. In connexion with this it will be recalled that half the volume of blood consists of fluid—and that this in the unretracted clot forms pools in which the microbes are, as in the supernatant serum of defibrinated blood, safe from phagocytic attack. The degree to which an individual clot is compacted by the spontaneous retraction of the fibrin meshwork depends, of course, upon all sorts of variable and incalculable factors.

Centrifugalisation—we may consider first the centrifuging of uncoagulated or defibrinated blood—altogether alters the distribution of the leucocytes in those bloods. When uncoagulated blood is centrifuged the large mononuclear leucocytes and the lymphocytes are brought to the surface, and are with a proportion of the blood-platelets agglomerated into a leucocytic cap. Most of the polynuclear leucocytes are assembled immediately underneath. When defibrinated blood is centrifuged for a long period (let us say, a quarter of an hour) in a high speed centrifuge, the polynuclear leucocytes are brought to the top. When microbes are implanted into serum or plasma or are implanted into blood which does not make immunising response, the microbes are not carried down in full proportion by ordinary centrifuging. Many are left in suspension in the supernatant fluid.

When a coagulated blood is centrifuged the clot is, of course, compacted, the lacunæ are abolished, and in the case of an implanted blood the microbes and leucocytes are brought into much closer proximity than in the uncompacted clot.

The results obtained by the centrifugalisation of implanted capillary clots furnish a striking manifestation of the influencing of the hæmobactericidal effect by mechanical factors.

Expt. 7.11.28. Comparison of Packed and Unpacked Blood and Slide Cells.—Four 50 c.mm. volumes of R. M. F.'s blood implanted with an 1800-fold and four others with a 600-fold dilution of staphylococcus, 2·5 c.mm. of staphylococcus dilution being added to each 50 c.mm. of blood. The implanted bloods were then filled into capillary tubes and were kept in the incubator for six minutes to allow time for clotting and for the separation of the clot. Then two tubes from each set of four were centrifuged for two minutes at full speed in the electric centrifuge. All the capillary tubes were then incubated for 18 hours. The clots were then decolorised and the anaerobic colonies in them were counted.

Four 50 c.mm. volumes of defibrinated blood to which the same addition of staphylococcus had been made were then cultured in slide cells. Higher dilutions of staphylococcus were enumerated in slide cells in watered blood. (Table VI.)

Having got these preliminary matters out of our way we may consider the outcome of repeating the fundamental experiments, varying however the technique, in using here for our implantation instead of defibrinated blood or blood fresh from the circulation, leucocytes derived from centrifuged blood suspended in serum. The following protocols of experiments show that we obtain when we operate with leucocytic suspensions exactly the same results as when we operate with the whole blood.

Expt. 31.10.30.—A. E. W.'s blood. Citrated blood was prepared by adding ½ per cent. of citrate of soda to 50 c.mm. volumes of blood. The blood samples were then centrifuged in capillary tubes and the plasma was pipetted off. The capillary tubes were now cut across immediately below the leucocytic cap and the agglomerated leucocytes dispersed in 30 c.mm. of serum. These serum suspensions of leucocytes were then implanted with, in each case, 5 c.mm. of a diluted staphylococcus culture, and were then incubated in capillary tubes disposed nearly horizontally. Similar quanta of staphylococcus were, for purposes of enumeration, implanted into leucocyte-free serum. (Table VIII.)

TABLE VIII.

Dilution of staphylococcus implanted.	No. of colonies which developed in a leucocyte-free serum.	No. of colonies which developed in the leucocytic suspension.	Percentage of survivors.

Staph./50,000	16 17 }16·5	2 2 }2	12
Staph./25,000	33	6 4 }5	15·5

Expt. 7.11 30.—50 c.mm. volumes of R. H.'s blood were centrifuged after the addition of ½ per cent. citrate of soda. The plasma having been pipetted off the leucocytes composing the leucocytic cap were dispersed in 30 c.mm. of serum and these suspensions were implanted with one-tenth of their volume of graduated dilutions of staphylococcus, and were then incubated in capillary tubes disposed nearly horizontally. (Table IX.)

TABLE IX.

36	9 12 }10½	28
72	20 18 }19	26
144	18 18 }18	12
288	58 30 }44	15
576	60 5 }59	10

Expt. 3.12.30. R. M. F.'s blood.—Graduated implantations of staphylococcus into a weak leucocytic suspension.

Leucocytic suspension prepared in bulk from R. M. F.'s citrated blood and diluted with serum to one-eighth standard; 2½ c.mm. volumes of staphylococcus dilutions were then implanted into 20 c.mm. of this leucocytic suspension—in triplicate and the suspensions were then incubated as above. Five counts made of 1/30,000 dilution in normal serum. (Table XI.)

We pass now to other experiments in which we employ, as before, graduated quanta of microbes, and operate again upon blood or separated leucocytes; but we now arrange our experiments so that the acquirement of bactericidal power of the serum and the effect exerted by it shall be separately manifest.

The simplest and most obvious way of achieving this is to bring the vaccine of dead or living microbes into operation upon the blood, to incubate the clots, and then pipette off the serum and test it by implanting it with *very small* numbers of living microbes.

TABLE XI.

Dilution of staphylococcus.	Count.	Calculated implant.	Colonies developed.	Percentage of survivors.
$\frac{\text{Staph.}}{1000}$	—	720	246 272 } 259	36
$\frac{\text{Staph.}}{3000}$	—	240	72 90 98 } 87	36
$\frac{\text{Staph.}}{10,000}$	—	72	32 33 22 } 29	40
$\frac{\text{Staph.}}{30,000}$	18 29 18 30 26	24	8 6 22 } 8	33
$\frac{\text{Staph.}}{100,000}$	—	7	5 6 7 } 6	86

Similar experiment and technique as above, 4.12.30.

Dilution of staphylococcus.	Count.	Calculated implant.	Colonies developed.	Percentage of survivors.
$\frac{\text{Staph.}}{10,000}$	91 81 103 93 78	89	6 3 12 4 } 6¼	7
$\frac{\text{Staph.}}{20,000}$	—	44	8 6 8 4 } 6½	14·8
$\frac{\text{Staph.}}{40,000}$	20 14 24 32	22¼	4 5 2 15 } 6½	29
$\frac{\text{Staph.}}{80,000}$	—	11	1 6 3 5 } 3¾	34
$\frac{\text{Staph.}}{160,000}$	—	6	3 3 2 1 } 2¼	37·5

The two following experiments are of this kind:—

Expt. 17.12.30. A. E. W.'s blood.—5 c.mm. of salt lution or diluted staphylococcus culture were incorporated to 50 c.mm. volumes of blood, and the bloods were then cubated for 20 minutes. After this they were centrifuged nd the sera pipetted off and tested by the Wash and After-ash method—the forerunner volume being here a 10 c.mm. blume of $\frac{\text{Staph.}}{1000}$ and the after-runner volumes three 5 c.mm. olumes of serum. The results were as shown in Table XII.

TABLE XII.

—	No. of colonies which developed in the three after-runner volumes.			Total.
	1	2	3	
Serum from control blood ..	27 26	20 27	13 15	60 68 } 64
Serum from blood implanted with—				
320 staph. per c.cm. ..	30	25	13	68
640 staph. per c.cm. ..	30	24	1	55
1290 staph. per c.cm. ..	23	16	10	49
2560 staph. per c.cm. ..	18	12	0	30

Calculation shows that here, in the most favourable case, the 15 c.mm. of serum here used acquired sufficient bactericidal power to kill at the rate of 2500 staphylococci per c.cm.

Expt. 2.12.30. A. E. W.'s blood.—50 c.mm. volumes of blood centrifuged after clotting. The sera were drawn off and were, after addition of Tuberculin B.E., reimposed upon the clots. After 24 hours' incubation the sera were a second time drawn off, and were tested by the Wash and Afterwash method, using a 5 c.mm. volume of $\frac{\text{Staph.}}{1000}$ as a forerunner and three 5 c.mm. volumes of serum as after-runners. (Table XIII.)

TABLE XIII.

—	No. of colonies which developed in the three after-runner volumes.			Total.
	1	2	3	
Control normal serum ..	24 34	15 13	4 6	43 53 } 48
Serum containing—				
$\frac{\text{B.E.}}{2000\text{ million}}$	13 21	7 6	4 4	24 31 } 27½
$\frac{\text{B.E.}}{1000\text{ million}}$	17 14	9 8	0 0	26 22 } 24
$\frac{\text{B.E.}}{500\text{ million}}$	18 22	3 12	2 3	23 37 } 30
$\frac{\text{B.E.}}{100\text{ million}}$	13 9	2 4	0 4	15 17 } 16
$\frac{\text{B.E.}}{50\text{ million}}$	15 16	8 5	5 0	28 21 } 24½
$\frac{\text{B.E.}}{25\text{ million}}$	8 9	10 3	7 2	25 14 } 19½

Calculation shows that here again in the most favourable cases the serum acquires sufficient bactericidal power to kill just over 2000 staphylococci per c.cm.

Expt. 21.3.30.—100 c.mm. volumes of A. E. W.'s uncoagulated blood implanted with 10 c.mm. of normal salt solution or staphylococcus culture were incubated for 25 minutes, and then centrifuged. The sera were now pipetted off. 5 c.mm. volumes of a 50,000-fold diluted staphylococcus culture were added in each case to 40 c.mm. of serum. (Table XIV.)

TABLE XIV.

—	No. of colonies which developed.
Serum of control blood .. .. (1)	51
(2)	50
Serum from blood vaccinated with—	
5 staph. per c.c.	39
50 staph. per c.c.	15
500 staph. per c.c.	22
1,000 staph. per c.c.	17
2,000 staph. per c.c.	17
5,000 staph. per c.c.	12
20,000 staph. per c.c.	26

The serum here killed off, at the best, 950 staphylococci per c.cm.

Another way of studying the effect of the serum separately is illustrated by the next two experiments.

Expt. 9.12.30. A. E. W.'s blood.—50 c.mm. volumes of blood centrifuged after clotting in capillary tubes. The sera were then drawn off, 2·5 c.mm. of diluted staphylococcus culture were added to each volume of serum, and the sera were then replaced on the clots and lightly centrifuged. The containing tubes were then disposed almost horizontally and incubated overnight. (Table XV.)

TABLE XV.

Dilution of staphylococcus culture implanted.	No. of microbes implanted into each volume of serum.	No. of colonies which developed.	Percentage of survivors.
$\frac{\text{Staph.}}{160,000}$	6	6 4 } 5	84
$\frac{\text{Staph.}}{80,000}$	12	2 6 } 4	32
$\frac{\text{Staph.}}{40,000}$	25	9 17 } 13	48
$\frac{\text{Staph.}}{20,000}$	50	21 19 } 20	40
$\frac{\text{Staph.}}{10,000}$	100	55 21 } 38	38

Calculation shows that here the serum in the most favourable case killed 2500 staphylococci per c.cm.

Expt. 23.9.30. A. E. W.'s blood.—50 c.mm. volumes were filled into capillary tubes and allowed to clot. They were then centrifuged and the sera pipetted off. The volumes of sera were then inoculated with Tuberculin B.E. and then implanted in each case with 58 staphylococci and replaced on the clots. The containing tubes were then sloped so as to form a small angle with the horizontal and were incubated in that position. The number of colonies which developed in the sera were then enumerated. (Table XVI.).

TABLE XVI.

—		No. of colonies which developed.
Control serum	(a) (b)	52 52 } 52
Serum containing—		
$\frac{\text{B.E.}}{\text{2400 million}}$		51 47 } 49
$\frac{\text{B.E.}}{\text{1200 million}}$		42 41 } 41½
$\frac{\text{B.E.}}{\text{600 million}}$		47 44 } 45½
$\frac{\text{B.E.}}{\text{300 million}}$		35 37 } 36

Calculation shows that the serum killed 640 staphylococci per c.cm.

Yet another way of arranging the experiment (there is also a fourth, which will be considered elsewhere) is as follows:—

We take a series of capillary tubes upon the stems of which we have marked off two segments of, let us say, 25 c.mm. capacity. We then fill into the distal segments blood from the finger, incubate for 20 to 30 minutes and then expel the clots. Having thus provided ourselves with capillary tubes divided into two segments, of which the distal one is carpeted with leucocytes and the proximal one uncarpeted, we introduce into these combined segments through the proximal ends of the tubes in each case a 50 c.mm. volume of serum—the sera employed for the purpose having been implanted with graduated quanta of staphylococcus. The tubes are now sealed up without displacing the columns of serum, and, the unlined segments being kept uppermost, are sloped so as to form a small angle with the horizontal; they are then placed in the incubator. The protocols of two experiments of this kind are subjoined.

Expt. 2.1.31. R. M. F.'s blood. (Table XVII.)

TABLE XVII.

Dilution of staphylococcus culture implanted into the serum.	No. of microbes suspended in the serum in the		No. of colonies which developed in the serum in the		Percentage of survivors in unlined segment.
	Lined segment	Unlined segment	Lined segment	Unlined segment	
$\frac{\text{Staph.}}{180{,}000}$	12	12	0 0	15 7 } 11	90
$\frac{\text{Staph}}{90{,}000}$	24	24	0 0	7 5 } 6	25
$\frac{\text{Staph.}}{30{,}000}$	72	72	0 0	33 34 } 33½	48
$\frac{\text{Staph.}}{10{,}000}$	216	216	0 0	73 82 } 77	30
$\frac{\text{Staph.}}{3{,}000}$	720	720	0 0	120 120 } 120	17

Here the serum in the unlined segment of the tubes killed in the most favourable case, 24,000 staphylococci per c.cm.

Experiment. A. E. W.'s blood. (Same technique as in the above.) (Table XVIII.)

TABLE XVIII.

Dilution of staphylococcus culture implanted into the serum.	No. of microbes suspended in the serum in the		No. of colonies which developed in the serum in the		Percentage of survivors in unlined segment.
	Lined segment	Unlined segment	Lined segment	Unlined segment	
$\frac{\text{Staph.}}{160{,}000}$	6	6	0 0	0 3 } 1·5	—
$\frac{\text{Staph.}}{80{,}000}$	12	12	0 0	12 9 } 10·5	87
$\frac{\text{Staph.}}{40{,}000}$	24	24	0 0	19 19 } 19	80
$\frac{\text{Staph.}}{20{,}000}$	48	48	0 0	38 34 } 36	75
$\frac{\text{Staph.}}{10{,}000}$	96	96	0 0	50 67 } 58	60
$\frac{\text{Staph.}}{5{,}000}$	192	192	0 0	73 70 } 71½	37

Here the serum in the unlined segment of the tubes killed in the most favourable case, 4800 staphylococci per c.cm.

When we review these experiments we recognise that *the law*—for we may now call it so—*of zero, or all but zero, bactericidal response to minimal microbic implantations, and of progressively greater response to increasing microbic stimulation*, holds not only of implantations into blood, but also of those made into leucocytic suspensions. And we have further seen that precisely similar effects are obtained with sera pipetted off from respectively lightly and heavily implanted bloods, and also with sera imposed upon respectively lightly and heavily vaccinated leucocytes.

The problem as to whether the increasing killing of serophytic microbes witnessed in effectively vaccinated blood is attributable to increased phagocytic response, or to a development of bactericidal powers in the serum, would appear herein to find its answer.

We shall have to consider later whether the increased phagocytic response which is concurrently obtained does or does not in cases where the action of phagocytes is not mechanically barred, contribute its quota to the observed result.

We may now, taking our cue from the experiments set out in Tables XIII. and XVI., dispose of one further general point before entering deeper into the question of phagocytic response in vitro. On studying the protocols in question you will note two outstanding points of difference between these and those previously considered. It will be noted, first, that instead of the vaccine being directly incorporated into the blood it was here merely placed in abutment against the blood clots. And it will be noted further, that the smaller and larger doses of vaccine here brought into application do not here, as they do when incorporated into the blood, produce opposite effects in the form of positive and negative responses. Instead of that we have here with an extensive range of doses (in the one case with doses ranging from 1 in 2000 million to 1 in 25 million, and in the other case with doses ranging from 1 in 2400 million to 1 in 300 million of Tuberculin B.E.) with every dose a positive bactericidal response.

There is not in reality any matter for surprise in this. For consideration will show that when a vaccine is merely superposed upon a clot there will, in the initial stages of the experiment, come into operation upon the leucocytes only such fraction of the total antigen as may diffuse into the clots. And in conformity with this there will, in the stage of the experiment we are considering, come into lethal operation upon the microbes disposed outside the clot, only the bactericidal substances elaborated in response to this first instalment of antigen.

A number of theoretically interesting points connected with this mode of bringing vaccines into application must be reserved for treatment in a separate paper, but it is of practical interest to reflect that the two contrasted methods of applying a vaccine which we have here been considering have their analogues, the one in intravenous administration and the other in subcutaneous application of vaccines. In the case of the first there is in respect to dosage very little margin of latitude. If we inject a little too much we produce an immediate negative phase. Contrariwise, where a vaccine is applied hypodermically the patient may, even in despite of the administration of an excessive dose, reap benefit om it. For the first instalment of antigen absorbed ay achieve the therapeutic aim we have in view, nd our aim once achieved any negative phase hich may thereafter supervene would be quite nnocuous.

INCREASED PHAGOCYTIC RESPONSE IN VITRO.

We may now pass to the consideration of the hagocytic response obtained in vitro.

Perhaps when all things are taken into consideration e most dramatic demonstrations of increased agocytic response obtained in vitro by vaccines e those which are obtained by the ruse of employing our phagocytic mixtures instead of unheated rum, heated serum—i.e., serum which is almost nuded of opsonin. It will suffice here to cite a gle experiment.

Expt. 5.5.30. A. E. W.'s defibrinated blood.—The blood s centrifuged. The serum was then pipetted off and ated for 45° to 60° C. The corpuscles were washed several mes in normal salt solutions. Two volumes of heated serum were then mixed with one volume of washed corpuscles and one volume of a six-fold diluted staphylococcus broth culture, and there was then added to the control phagocytic mixture one wash of physiological salt solution, and to the other mixtures in each case one wash of a dilution of Tuberculin B.E. These mixtures were then, after incubation for 20 minutes, centrifuged and recentrifuged for 45″ in each direction. Phagocytic films were then made from each sample of blood. (Table XIX.)

TABLE XIX.

= Percentage of leucocytes which phagocytose.
= Percentage of leucocytes containing an uncountable number of staph.

—	Phagocytic.		A	B
	Count.	Index		
Heated serum + corp's + $\frac{\text{staph.}}{6}$ + 1 Wash of normal salt	2 3·3 } 2·6	1	42 57	5 5
Heated serum + corp's + $\frac{\text{staph.}}{6}$ + 1 Wash (= 1/100th) of $\frac{\text{B.E.}}{\text{256 million}}$	6	2·3	58	16
" " " $\frac{\text{B.E.}}{\text{128 million}}$	2·6	1	10	8
" " " $\frac{\text{B.E.}}{\text{64 million}}$	7·7	3	67	21
" " " $\frac{\text{B.E.}}{\text{32 million}}$	10	3·9	66	19
" " " $\frac{\text{B.E.}}{\text{16 million}}$	7·1	2·8	60	21
" " " $\frac{\text{B.E.}}{\text{8 million}}$	6·1	2·3	49	21
" " " $\frac{\text{B.E.}}{\text{4 million}}$	12·0	4·6	88	48
" " " $\frac{\text{B.E.}}{\text{2 million}}$	5·6	2·2	56	18

In order to appraise at their proper value the figures set down in the first two columns of the above protocol account has to be taken of the fact that in counting the films any ingest of over 20 staphylococci was entered as an ingest of 20. If it had been possible to count the full number of microbes ingested (the percentage of leucocytes containing uncountable numbers is recorded in column 4 of the protocol) the phagocytic indices would have come out very much higher. The phagocytic counts with the optimum additions of vaccine would certainly have reached astonishing figures—let us say an average of 30 or 40 per cell, and the phagocytic indices would have reached 7·5 or 10.

An experiment like the foregoing furnishes conclusive evidence that leucocytes when treated with vaccines, respond, not only (as seen in previous experiments) by excreting bactericidal substances into the serum, but also by an increased phagocytosis. Similar, but owing to the larger phagocytic intake in the control, quantitatively less striking differences between the vaccinated bloods and the controls are obtained by adding appropriate quanta of vaccines to phagocytic mixtures containing, instead of heated, unheated serum. And analysis of these results by the chiastic method has shown that increased phagocytic response obtained is, in most cases, due to a combination of increased opsonic power developed in the serum and to increased phagocytic avidity in the leucocytes. Not infrequently, however, the opsonic power of the serum is increased, while the phagocytic avidity of the leucocytes is reduced; and again, sometimes the phagocytic avidity of the leucocytes is increased while the opsonic power of the serum remains the same or is reduced.

There is, however, in these respects, very little agreement between one experiment and another, and very little also between the figures which represent the phagocytic index of a blood and its component factors—i.e., the figures which represent (*a*) the opsonic index of the serum, and (*b*) the phagocytic avidity of the leucocytes. This is no doubt due to the fact that the washing, centrifuging, and standing in salt solution to which the leucocytes are exposed in chiastic and opsonic experiments all affect their intake, and it is probably also due to the serum of vaccinated bloods containing, in addition to opsonins, antigens which can evoke immunising response in the leucocytes used for testing. There is at this stage no need, I think, to labour the point that the leucocytes of a phagocytic mixture are responsive elements, and are not, in any sense, the analogues of chemical indicators.

IMPORTANCE OF THE FACTOR OF PHAGOCYTOSIS.

I now pass to consider certain general problems which require to be carefully pondered.

The first of these is the problem—already envisaged above—as to whether enhanced phagocytosis or the development of bactericidal power in the blood-fluids is the more important factor in the immunising response which eventuates in increased killing of serophytic microbes in the blood. In connexion with this arithmetical considerations make clear that inasmuch as the blood normally contains 7½ millions of leucocytes per c.cm. there would, if we implanted 100 microbes per c.cm. (and 100 microbes per c.cm. represents a formidable septicæmic infection) be an army of 75,000 leucocytes available for the phagocyting of each microbe.

The same sort of considerations apply to the opsonic capacity of the normal blood fluids. That opsonic capacity as measured (rightly or wrongly) by the ordinary phagocytic technique[14] easily permits of ingests of 10 to 20 microbes per leucocyte of normal phagocytic avidity—and to a total of 75 and 150 millions of microbes ingested per c.cm.

It will be obvious from these data that the normal blood already possesses a phagocytic capacity far in excess of all conceivable requirements. It follows that the explanation of inadequate phagocytosis of implanted or infecting microbes must be sought in the difficulty of leucocytic access to the implanted microbes. When we meditate upon these things and reflect that chemical access (that is access of dissolved bactericidal substances) to implanted microbes must, in the nature of things, be more easily realisable than leucocytic access, and consider further that such chemical access is, in the case of the circulating blood, secured, it comes home to us convincingly that the development of an even moderate amount of bactericidal power in the serum must count for more in the killing of serophytic microbes than any reinforcement of phagocytosis.

The further questions we have to consider are: (1) the question of immediate (I have before called it "*subitaneous*") immunising response; (2) the question of specific or non-specific immunity (we shall see that specific and non-specific are ambiguous terms); and lastly (3) the question of dosage.

THE IMMEDIATE RESPONSE.

One of the things I had to do in connexion with antityphoid inoculation was to refute with data obtained by measuring the bactericidal power of inoculated men before and after inoculation, the traditional belief that ten days must go over before the effect of a vaccination process becomes manifest. I showed there that the effect of inoculation upon the blood was already plainly manifest 24 hours after the administration of the vaccine. A further scaling down of the time deemed requisite for the manifestation of the effects of inoculation was achieved when it emerged from our measurements of the opsonic index that the effects of subcutaneous inoculation and after auto-inoculation were already well developed within an hour after the application of the ictus immunisatorius. And further research has shown that immunising response to vaccines is, in the case of intravenous inoculations, well developed within 10 minutes after the inoculation, and finally, both bactericidal and phagocytic experiments on the blood in vitro—which, of course, lend themselves better to accurate timing—have shown that there is instantaneous response to the introduction of vaccines into the blood. You will, when we come to consider the question of dosage, see that the time requisite for the development of maximum immunising response is not a simple function of the quantum of antigen incorporated, but is largely determined by the soluble or insoluble nature of the antigen and the lytic forces which the blood brings to bear upon it.

(*To be concluded.*)

---

[14] It will be shown elsewhere that quite different results are obtained when we employ (and the centrifugalisation method makes this possible) plasma instead of serum in our opsonic measurements.

SAVERNAKE HOSPITAL CONTRIBUTORY SCHEME.—Of this hospital's income of £10,471 last year, £4122 was raised by the contributory scheme—£1000 more than its total income ten years ago. The scheme has 4186 branch secretaries and collectors.

INJECTION TREATMENT OF VARICOSE VEINS AND ITS BEARING ON THE PROBLEMS OF THROMBOSIS.*

BY DAVID H. PATEY, M.S. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE MIDDLESEX HOSPITAL.

THE injection treatment has within a short space of time so altered our previous ideas on the treatment of varicose veins that it may without exaggeratio be described as revolutionary. There are fashions in medicine as in all things, but injection treatment has by now been widely tested, and the results have been found satisfactory by so many observers th its position in therapeutics may be regarded established. The mode of action of the vario solutions used therefore has an immediate practical interest. But there is an aspect other than th therapeutic, and that is: what effect, if any, has th new method of treatment had on our outlook on th problems of spontaneous thrombosis?

The subject may be conveniently considered unde three headings: (*a*) The pathological changes resultin from injections and their explanation. (*b*) Th relation between thrombosis produced by injectio and spontaneous thrombosis. (*c*) The possible com plications of injection treatment.

Pathological Changes after Injection.

In man the opportunity does not often occur making a series of histological observations at regu intervals after injection, so that these changes most conveniently studied in animals. The margi ear-vein of the rabbit has been most often used this purpose, since it is a comparatively large v lending itself to continuous observation after injection. But, while most of the recorded exp ments deal with the changes at long intervals a the injections (Binet and Verne, Kern and Angle), is the earlier changes that are important in determini the cause of the venous obliteration, and it is chie with these that this paper will deal.

In the first series of experiments, the margi ear-veins of a number of animals were injected wi 1 c.cm. of a 30 per cent. solution of sodium salicylate. The animals were killed at regular intervals and specimens thus obtained showing the microscopical appearances $\frac{1}{4}$ hour and $\frac{1}{2}$ hour after injection, then at half-hourly intervals up to six hours, then at hourly intervals up to 12 hours, and finally at 24 hours. The immediate naked-eye effect of the injections was a general dilatation of the vessels of the ear, which as a result showed a diffuse pinkish blush. By 15 minutes as a rule the circulation in the injected vein had ceased, owing to intravascular coagulation. After some hours, and especially at 24 hours, the whole ear had become swollen and œdematous. Microscopically, the earliest change to be seen in the vein wall was a slight wrinkling and deposit of blood-pigments in the endothelial cells lining the vein (Fig. 1), while the vein valves also seemed liable to early damage (Fig. 2). But in some of these early specimens, in spite of the presence of intravascular clotting, a considerable amount of normal, apparently intact, endothelial lining could be seen (Fig. 1). Later, the endothelium tended to degenerate and disappear, the vein wall stained poorly, and occasionally became fragmented (Fig. 3), and by 24 hours the thin vein wall was almost completely destroyed. For the first few hours after injection the tissues surrounding the veins showed no change, but later a progressively increasing infiltration with polymorphonuclear leucocytes could be seen (Fig. 4).

---

* Based on a Hunterian lecture delivered before the Royal College of Surgeons of England on Jan. 26th, 1931.

The histological changes following the intravenous injection of 30 per cent. sodium salicylate in the rabbit thus fall roughly into three stages: (1) intravascular coagulation; (2) destructive changes in the vein wall; (3) acute inflammatory changes in the surrounding tissues.

The significance of these histological changes will be discussed later, but it may be said that in these animal experiments intravascular clotting occurs when the vein wall is little altered, and before the histological signs of acute inflammation have developed.
